Introduction

Dark matter¹ has not yet been observed in particle physics experiments, and there is not yet any evidence for non-gravitational interactions between dark matter and Standard Model particles. If such interactions exist, particles of dark matter could be produced at the LHC. Since dark matter particles themselves do not produce signals in the LHC detectors, one way to observe them is when they are produced in association with a visible SM particle $X(=g, q, \gamma, Z, W, \text{ or } h)$. Such reactions, which are observed at colliders as particles or jets recoiling against an invisible state, are called “mono- X ” or \cancel{E}_T+X reactions [FSTo6, BHK⁺10, BFH10], where \cancel{E}_T is the missing transverse momentum observable in the detector.

Early LHC Run-1 searches for \cancel{E}_T+X signatures at ATLAS [ATL15d, ATL15c, ATL14c, ATL14b, ATL14a, ATL15b, ATL15a, ATL14d] and CMS [CMS14a, CMS14b, CMS15c, CMS15b, CMS15d, CMS14c, CMS15a] employed a basis of contact interaction operators in effective field theories (EFTs) [GIR⁺11, GIR⁺10] to calculate the possible signals. These EFTs assume that production of dark matter takes place through a contact interaction involving a quark-antiquark pair, or two gluons, and two dark matter particles. In this case, the missing energy distribution of the signal is determined by the nature and the mass of the dark matter particles and the Lorentz structure of the interaction. Only the overall production rate is a free parameter to be constrained or measured. Provided that the contact interaction approximation holds, these EFTs provide a straightforward way to compare the results from different collider searches with non-collider searches for dark matter. From the time of their proposal, however, it was clear that, though limits on the contact interaction operators provide useful information, they are not always a good description of dark matter production at the LHC in the regime of interest [GIR⁺11, SV12].

The contact interaction interpretation of Tevatron [A⁺12a] and Run-1 LHC searches provided results outside the range of applicability of the EFT description, requiring further study [BFH10, Kop11, FHKT11, FHKT12, SV12, BDSMR14]. Some “simplified models” [ASTo9, GS11, A⁺12b] of dark matter production were constructed, including particles and interactions beyond the SM. These models can be used consistently at LHC energies, and pro-

¹ Many theories of physics beyond the Standard Model predict the existence of stable, neutral, weakly-interacting and massive particles that are putative dark matter candidates. In the following, we refer to such matter as dark matter, even though the observation of such matter at a collider could only establish that it is neutral, weakly-interactive, massive and stable on the distance-scales of tens of meters.

vide an extension to the EFT approach. Many proposals for such models have emerged (see, for example Refs. [AJW₁₂, AHW₁₃, DNRT₁₃, BDM₁₄, BB₁₃, BB₁₄, AWZ₁₄, A⁺_{14a}, MMA⁺₁₄, HKSW₁₅, BFG₁₅, HR₁₅, BT₁₃, CNS⁺₁₃, BDG⁺₁₂, PS₁₄, CDM⁺₁₄]). These models introduce a new particle: a mediator of the interactions between SM and DM particles. At the LHC, the kinematics of mono-X reactions occurring via a TeV-scale mediator can differ substantially from the prediction of the contact interaction. The mediator may also produce qualitatively different signals, such as decays back into Standard Model particles. Thus, appropriate simplified models are thus an important component of the design, optimization, and interpretation of dark matter searches at ATLAS and CMS.

1.1 The ATLAS/CMS Dark Matter Forum

To understand what signal models should be used for the upcoming LHC Run 2, groups of experimenters from both ATLAS and CMS collaborations have held separate discussions with small groups of theorists [MMA⁺₁₄, A⁺_{14a}]. Another joint discussion was held at the DM@LHC workshop in Oxford, in September 2014 [par]. Following the DM@LHC workshop, ATLAS and CMS organized a forum, called the *ATLAS-CMS Dark Matter Forum*, to form a consensus on the use of simplified models and EFTs for Run-2 with the participation of experts on theories of dark matter. This is the final report of that forum.

One of the guiding principles of this report is to channel the efforts of the ATLAS and CMS collaborations towards a minimal basis of dark matter models that should influence the design of the early Run-2 searches. At the same time, a thorough survey of realistic collider signals of dark matter is a crucial input to the overall design of the search program.

The goal of this report is such a survey, though confined within some broad assumptions and focused on benchmarks for kinematically-distinct signals which are most urgently needed. As far as time and resources have allowed, the assumptions have been carefully motivated by theoretical consensus and comparisons of simulations. But, to achieve a true consensus in only a few months before the start of Run-2, it was important to restrict the scope and timescale to the following:

1. The forum should propose a prioritized, compact set of benchmark simplified models that should be agreed upon by both collaborations for Run-2 searches. The values for the scan on the parameters of the models for which experimental results are provided should be specified, to facilitate theory reinterpretation beyond the necessary model-independent limits that should be provided by all LHC Dark Matter searches.
2. The forum should standardize the event generator implementation of the simplified models and harmonize other common

technical details as far as practical. It would be desirable to have a common choice of LO/NLO, ME-parton shower matching and merging, factorization and renormalization scales for each of the simplified models. This will also lead to a common set of theory uncertainties, which will facilitate the comparison of results between the two collaborations.

3. The forum could also discuss how to apply the EFT formalism and present the results of EFT interpretations.
4. The forum should prepare a report summarizing these items, suitable both as a reference for the internal ATLAS and CMS audiences and as an explanation of Run-2 benchmarks for theory and non-collider readers. This report represents the views of the participants of the forum.

1.2 Grounding Assumptions

We assume that interactions exist between Standard Model hadrons and the particles that constitute cosmological dark matter. If this is not the case, then proton collisions will not produce dark matter particles, and dark matter will not scatter off nuclei in direct detection experiments.

The Dark Matter itself is assumed to be a single particle, a Dirac fermion WIMP, stable on collider timescales and non-interacting with the detector. The former assumption is reductionistic. The rich particle content of the Standard Model is circumstantial evidence that the dark matter sector, which constitutes five times as much of the mass of the universe, may be more complex than a single particle or a single interaction. But, as was often the case in the discoveries of the SM, here only one mediator and one search channel might play a dominant role in the opening stages of an LHC discovery. The latter assumption focuses our work on early LHC searches, where small kinematic differences between models will not matter in a discovery scenario, and with the imminent re-start of the LHC our report relies heavily on a large body of existing theoretical work which assumed Dirac fermionic dark matter.

Different spins of dark matter particles will typically give similar results. Some exceptions exist. For example, the choice of Dirac fermions forbids some processes that are allowed for Majorana fermions [GIR⁺11]. Aside from these, adjusting the choice of Dirac or Majorana fermions or scalars will produce only minor changes in the kinematic distributions of the visible particle and is expected to have little effect on cut-and-count² analysis. Thus the choice of Dirac fermion dark matter should be sufficient as benchmarks for the upcoming Run-2 searches.

One advantage of collider experiments lies in their ability to study and possibly characterize the mediator. A discovery of an anomalous \cancel{E}_T signature at the LHC would not uniquely imply discovery of dark matter, while at the same time discovery of an

² Cut-and-count refers to an analysis that applies a certain event selection and checks the inclusive number of events which pass. This is to be contrasted with a shape analysis, which compares the distribution of events.

anomalous and annually-modulated signal in a direct-detection experiment would leave unanswered many questions about the nature of the interaction that could be resolved by the simultaneous discovery of a new mediator particle. Collider, direct, and indirect detection searches provide complementary ways to approach this problem, and it is in this spirit that much of our focus is on the mediator.

We systematically explore the basic possibilities for mediators of various possible spins and couplings. All models considered are assumed to produce a signature with pairs of dark matter particles. Though more varied and interesting possibilities are added to the literature almost daily, these basic building blocks account for much of the physics studied at hadron colliders in the past three decades.

We also assume that Minimal Flavor Violation (MFV) [CG87, HR90, BGG⁺01, DGI02] applies to the models included in this report. This means that the flavor structure of the couplings between dark matter and ordinary particles follows the same structure as the Standard Model. This choice is simple, since no additional theory of flavor is required, beyond what is already present in the SM, and it provides a mechanism to ensure that the models do not violate flavor constraints. As a consequence, spin-0 resonances must have couplings to fermions proportional to the SM Higgs couplings. Flavor-safe models can still be constructed beyond the MFV assumption, for example [ABG14], and deserve further study.

In the parameter scan for the models considered in this report, we make the assumption of a minimal decay width for the particles mediating the interaction between SM and DM. This means that only decays strictly necessary for the self-consistency of the model (e.g. to DM and to quarks) are accounted for in the definition of the mediator width. We forbid any further decays to other invisible particles of the Dark Sector that may increase the width or produce striking, visible signatures. Studies within the Forum show that, for cut-and-count analyses, the kinematic distributions of many models, and therefore the sensitivity of these searches, do not depend significantly on the mediator width, as long as the width remains smaller than the mass of the particle and that narrow mediators are sufficiently light.

The particle content of the models chosen as benchmarks is limited to one single kind of DM whose self-interactions are not relevant for LHC phenomenology, and to one type of SM/DM interaction at a time. These assumptions only add a limited number of new particles to the SM. These simplified models, independently explored by different experimental analyses, can be used as starting points to build more complete theories. Even though this factorized picture does not always lead to full theories and leaves out details that are necessary for the self-consistency of single models (e.g. the mass generation for mediator particles), it is a starting point to prepare a set of distinct but complementary collider searches for Dark Matter, as it leads to benchmarks that are easily comparable

across channels.

1.3 Choices of benchmarks considered in this report and parameter scan

Contact interaction operators have been outlined as basis set of theoretical building blocks representing possible types of interactions between SM and DM particles in [GIR⁺10]. The approach followed by LHC searches (see e.g. Refs. [CMS14a, ATL15d] for the most recent jet+ E_T Run-1 searches with the 8 TeV dataset) so far has been to simulate only a prioritized set of the possible operators with distinct kinematics for the interpretation of the constraints obtained, and provide results that may be reinterpreted in terms of the other operators. This report intends to follow this strategy, firstly focusing on simplified models that allow the exploration of scenarios where the mediating scale is not as large. In the limit of large mediator mass, the simplified models map onto the EFT operators. Secondly, this report considers specific EFT benchmarks whenever neither a simplified model completion nor other simplified models yielding similar kinematic distributions are available. This is the case for dimension-5 or dimension-7 operators with direct Dark Matter-electroweak boson couplings. Considering these models as separate experimental benchmarks will allow to target new signal regions and help validate the contact interaction limit of new simplified models developed to complete these specific operators.

In all cases, experimental searches should deliver results that are independent from the specific benchmark tested. Furthermore, it should be possible to map results from simplified models to contact operators, in the high mediator mass limit. Results from EFT benchmarks should include the condition that the momentum transfer does not probe the scale of the interaction; whenever there is no model that allows a direct mapping between these two quantities, various options should be tested to ensure a given fraction of events within the range of applicability of the EFT approach.

This report does not quantitatively consider constraints ‘external’ to the MET+X analyses coming from the LHC experiments themselves, such as searches for mediator decays, when choosing the points to be scanned in the parameter space of the models. The main reason for not doing so in this report is the difficulty of incorporating these constraints in a rigorous quantitative way within the timescale of the Forum. However, even if the parameter scans and the searches are not optimized with those constraints in mind, we intend to make all information available to the community to exploit the unique sensitivity of colliders to all possible Dark Matter signatures.

1.4 *Structure of this report*

Chapter 2 of the report is dedicated to simplified models with radiation of a hard object either from the initial state or from the mediator. These models produce primarily monojet signatures, but should be considered for all \cancel{E}_T+X searches. Chapter 3 contains the benchmark model recommendations and choices for final states specifically containing an electroweak boson ($W/Z/\gamma/H$). In this case, both simplified models leading to mono-boson signatures and contact interaction operators are considered. Details of the implementation of the simplified models in Monte Carlo generators are provided in Chapter 4. Chapter 5 is devoted to the treatment of the presentation of results for the benchmark models from contact interaction operators. Chapter 6 prescribes how to estimate theoretical uncertainties on the simulation of these models. Chapter 7 concludes the report.

The technical implementation and further models that can be studied beyond early searches are described in Appendix A. For these models, either the implementation could not be fully developed by the time of this report, or some of the grounding assumptions were not fully met. Some of these models have been used in previous ATLAS and CMS analyses and discussed thoroughly within the Forum. They are therefore worth considering for further studies and for Run-2 searches, since they lead to unique \cancel{E}_T+X signatures that are not produced by any other of the models included in this report.

Appendix B contains the necessary elements that should be included in the results of experimental searches to allow for further reinterpretation.

Simplified models for all $E_T + X$ analyses

In this Chapter we review models that yield $X + E_T$ signatures, where X is a QCD parton or γ, W, Z or h .

The primary simplified models for Dirac fermion DM endorsed by this Forum are detailed in this Chapter, comprising spin-0 and spin-1 mediators. Section 2.1 covers the s -channel exchange of a vector mediator¹, while we consider both s -channel and t -channel exchange for scalar mediators in Section 2.2 and 2.3 respectively. Spin-2 mediators are briefly mentioned in Section 2.4. While these models are general and cover a broad set of signatures, the discussion and studies are focused on the monojet final state. Details on final states with EW boson radiation and with heavy flavor quarks from diagrams arising within these models are also discussed in this Chapter.

The simplified model where a vector mediator is exchanged in the s -channel is known to NLO accuracy in the case of DM pair production in association to one parton [HKR13]. All other models are currently known to leading order. Section 4 details the recommended implementation of these models that have been used for the studies in this Chapter. A summary of the recommendation of the generation of this model is provided in Table 6.1.

¹ Colored vector mediators can be exchanged in the t -channel, but there are no examples in literature so far.

2.1 Vector and axial vector mediator, s -channel exchange

A simple extension of the Standard Model (SM) is an additional $U(1)$ gauge symmetry, where a dark matter (DM) candidate particle has charges only under this new group. Assuming that some SM particles are also charged under this group, a new gauge boson can mediate interactions between the SM and DM.

We consider the case of a DM particle χ of mass m_{DM} that is a Dirac fermion and where the production proceeds via the exchange of a spin-1 mediator of mass M_{med} in the s -channel, illustrated in Fig. 2.1.

We consider two models with vector and axial-vector couplings between the spin-1 mediator Z' and SM and DM fields, with the corresponding interaction Lagrangians:

Figure 2.1: Representative Feynman diagram showing the pair production of dark matter particles in association with a parton from the initial state via a vector or axial-vector mediator. The cross section and kinematics depend upon the mediator and dark matter masses, and the mediator couplings to dark matter and quarks respectively: $(M_{\text{med}}, m_{\text{DM}}, g_{\text{DM}}, g_q)$.

$$\mathcal{L}_{\text{vector}} = g_q \sum_{q=u,d,s,c,b,t} Z'_\mu \bar{q} \gamma^\mu q + g_{\text{DM}} Z'_\mu \bar{\chi} \gamma^\mu \chi \quad (2.1)$$

$$\mathcal{L}_{\text{axial-vector}} = g_q \sum_{q=u,d,s,c,b,t} Z'_\mu \bar{q} \gamma^\mu \gamma^5 q + g_{\text{DM}} Z'_\mu \bar{\chi} \gamma^\mu \gamma^5 \chi. \quad (2.2)$$

The coupling g_q is assumed to be universal to all quarks. As mentioned in the Introduction, when no additional visible or invisible decays contribute to the width of the mediator, the minimal width is fixed by the choices of couplings g_q and g_{DM} . The effect of larger widths is discussed in Section 2.5.2. For the vector and axial-vector models, the minimal width is:

$$\Gamma_{\text{min}}^V = \frac{g_{\text{DM}}^2 M_{\text{med}}}{12\pi} \left(1 + \frac{2m_{\text{DM}}^2}{M_{\text{med}}^2} \right) \beta_{\text{DM}} \theta(M_{\text{med}} - 2m_{\text{DM}}) \quad (2.3)$$

$$+ \sum_q \frac{3g_q^2 M_{\text{med}}}{12\pi} \left(1 + \frac{2m_q^2}{M_{\text{med}}^2} \right) \beta_q \theta(M_{\text{med}} - 2m_q),$$

$$\Gamma_{\text{min}}^A = \frac{g_{\text{DM}}^2 M_{\text{med}}}{12\pi} \beta_{\text{DM}}^{3/2} \theta(M_{\text{med}} - 2m_{\text{DM}}) \quad (2.4)$$

$$+ \sum_q \frac{3g_q^2 M_{\text{med}}}{12\pi} \beta_q^{3/2} \theta(M_{\text{med}} - 2m_q).$$

$\theta(x)$ denotes the Heaviside step function, and $\beta_f = \sqrt{1 - \frac{4m_f^2}{M_{\text{med}}^2}}$ is the velocity of the fermion f with mass m_f in the mediator rest frame. Note the color factor 3 in the quark terms. Figure 2.2 shows the minimal width as a function of mediator mass for both vector and axial-vector mediators assuming $g_q = g_{\text{DM}} = 1$. With this choice of the couplings, the dominant contribution to the minimal width comes from the quarks, due to the combined quark number and color factor enhancement. We specifically assume that the vector mediator does not couple to leptons. If such a coupling were present, it would have a minor effect in increasing the mediator width, but it would also bring in constraints from measurements of the Drell-Yan process that would unnecessarily restrict the model space.

Therefore, the minimal set of parameters under consideration for these two models is

$$\{m_{\text{DM}}, M_{\text{med}}, g_q, g_{\text{DM}}\}. \quad (2.5)$$

Figure 2.2: Minimal width as a function of mediator mass for vector and axial-vector mediator assuming couplings of 1. The total width is shown as solid lines for Dark Matter masses of 10 GeV, 30 GeV, 100 GeV and 300 GeV in black, red, brown and green, respectively. The individual contributions from Dark Matter are indicated by dotted lines with the same colors. The contribution from all quarks but top is shown as magenta dotted line and the contribution from top quarks only is illustrated by the dotted blue line. The dotted black line shows the extreme case $\Gamma_{\text{min}} = M_{\text{med}}$.

See [BDMM15] for a thorough discussion of these models.

2.1.1 Spin structure of the couplings

In this section, the differences between the vector and axial-vector models are described. Furthermore, it is possible to consider other models in which mixed vector and axial-vector couplings are considered, for instance the couplings to the quarks are axial-vector whereas those to DM are vector. Such comparisons are also presented.

The samples with pure vector and pure axial-vector couplings are compared for $M_{\text{med}} = 100$ GeV and different Dark Matter masses in Fig. 2.3. No differences in the shape of the \cancel{E}_T distributions are observed between the samples with coincident masses. In the case of the on-shell Dark Matter pair production where $2m_{\text{DM}} \ll M_{\text{med}}$, the cross sections of the pure vector and pure axial-vector models are similar. With increasing Dark Matter mass towards the $2m_{\text{DM}} = M_{\text{med}}$ transition and beyond into the off-shell production regime, the relative difference between the cross sections of the two samples is increasing, with the vector samples having larger cross sections.

Figure 2.3: Comparison of the pure vector and pure axial-vector couplings. The \cancel{E}_T distribution is shown for the samples generated with $M_{\text{med}} = 100$ GeV and different Dark Matter masses. Ratios of the normalized distributions are shown for between the samples with coincident masses. A_{300} and A_{500} in the table denote the acceptance of the $\cancel{E}_T > 300$ GeV and $\cancel{E}_T > 500$ GeV cut, respectively.

Figure 2.4 shows the samples generated with pure and mixed couplings for $m_{\text{DM}} = 100$ GeV and $M_{\text{med}} = 1$ TeV, i.e. where the Dark Matter pair is produced on-shell. The mediator width between the pure vector and pure axial-vector couplings differ only by 2% in this case, and < 10% agreement between the cross sections is found. The mediator widths for the samples with the same type coupling to quarks agree at better than 1% since the width is dominated by the quark contribution, as expected from Eq. 2.3. No significant differences between the samples with same type Dark Matter coupling are seen, given the statistical precision of the generated samples. This is expected since the mediator is produced

on-shell, and the details of the invisible decay are unimportant in cut-and-count searches.

For the off-shell Dark Matter pair production, shown in Fig. 2.5 for $m_{\text{DM}} = 100$ GeV and $M_{\text{med}} = 100$ GeV, there is approximately a factor 2 difference between the cross-sections of the samples with pure couplings is observed. As in the previous case, the samples with the same type coupling to Dark Matter are similar both in terms of cross sections and \cancel{E}_T shape. Since the contribution to the mediator width from Dark Matter is closed in this case, only the quark couplings define the width. Only couplings to light quarks are opened in the case of $M_{\text{med}} = 100$ GeV for which the differences between the partial widths of vector and axial-vector couplings are marginal. This explains the similar minimal widths for all four samples stated in Fig. 2.5.

In general, the coupling to quarks is not expected to play an important role as it is only needed to produce the mediator which is confirmed by the observations above. For scalar and psuedoscalar mediators, the coupling to Dark Matter determines the form of the matrix element which explains the similarity of the samples with the same type Dark Matter couplings. Based on these arguments, we recommend to consider only the models with pure vector couplings or pure axial-vector couplings.

Figure 2.4: Comparison of the pure vector, V-V, and pure axial-vector, A-A, couplings with mixed couplings, A-V and V-A where the first (second) letter indicates the Standard Model (Dark Sector) vertex. The \cancel{E}_T distribution is shown for the samples generated with $m_{\text{DM}} = 100$ GeV and $M_{\text{med}} = 1$ TeV. Ratios of the normalized distributions are shown for A-V over V-V and for V-A over A-A. A_{300} and A_{500} in the table denote the acceptance of the $\cancel{E}_T > 300$ GeV and $\cancel{E}_T > 500$ GeV cut, respectively.

2.1.2 Parameter scan

In order to determine an optimal choice of the parameter grid for the simulation of early Run-2 benchmark models, dependencies of the kinematic quantities and cross sections on the model parameters have been studied. The following paragraphs list the main observations from the scans over the parameters that support the final proposal for the benchmark signal grid.

Figure 2.5: Comparison of the pure vector, V-V, and pure axial-vector, A-A, couplings with mixed couplings, A-V and V-A where the first (second) letter indicates the Standard Model (Dark Sector) vertex. The E_T distribution is shown for the samples generated with $m_{\text{DM}} = 100$ GeV and $M_{\text{med}} = 100$ GeV. Ratios of the normalized distributions are shown for A-V over V-V and for V-A over A-A. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

Scan over the couplings To study the dependence of kinematic distributions on the coupling strength, samples were generated where a pair of $m_{\text{DM}} = 10$ GeV Dark Matter particles is produced on-shell from the mediator of $M_{\text{med}} = 1$ TeV. Figure 2.6 compares the shapes of the E_T distribution for the different choices of the coupling strength. This is a generator-level prediction with no kinematic selections or detector simulation. Coupling values in the scan range 0.1–1.45, fixing $g_q = g_{\text{DM}}$, correspond to a rough estimate of the lower sensitivity of mono-jet analyses and a maximum coupling value such that $\Gamma_{\text{min}} < M_{\text{med}}$. We observe that the shapes of the E_T or jet p_T distributions do not depend on the couplings (and consequently the width) in the ranges considered. A large width of the mediator implies a broad integral over the contributing parton distributions, which might not be well approximated by the midpoint of this integral. This study shows that the effect, in the p_T distribution of the observed gluon, is not important.

Based on similar findings for different choices of M_{med} and m_{DM} , we conclude that the shapes of kinematic distributions are not altered by coupling variations, neither for the on-shell Dark Matter production where $M_{\text{med}} > 2m_{\text{DM}}$, nor for the off-shell Dark Matter production where $M_{\text{med}} < 2m_{\text{DM}}$. Only the production cross sections change. Differences in kinematic distributions are expected only close to the transition region where both on-shell and off-shell decays occur.

Special care needs to be taken when coupling strengths are combined with extremely heavy mediators. Figure 2.7 suggests a change in the shape of the E_T distribution for a $M_{\text{med}} = 5$ TeV mediator once $\Gamma_{\text{min}}/M_{\text{med}}$ is of the order of a percent or lower. Such heavy mediators, although inaccessible by the LHC data, are interesting since they provide a good approximation for benchmark EFT models. The observed difference among the simplified models in the plot arises from the fact that the region of low invariant

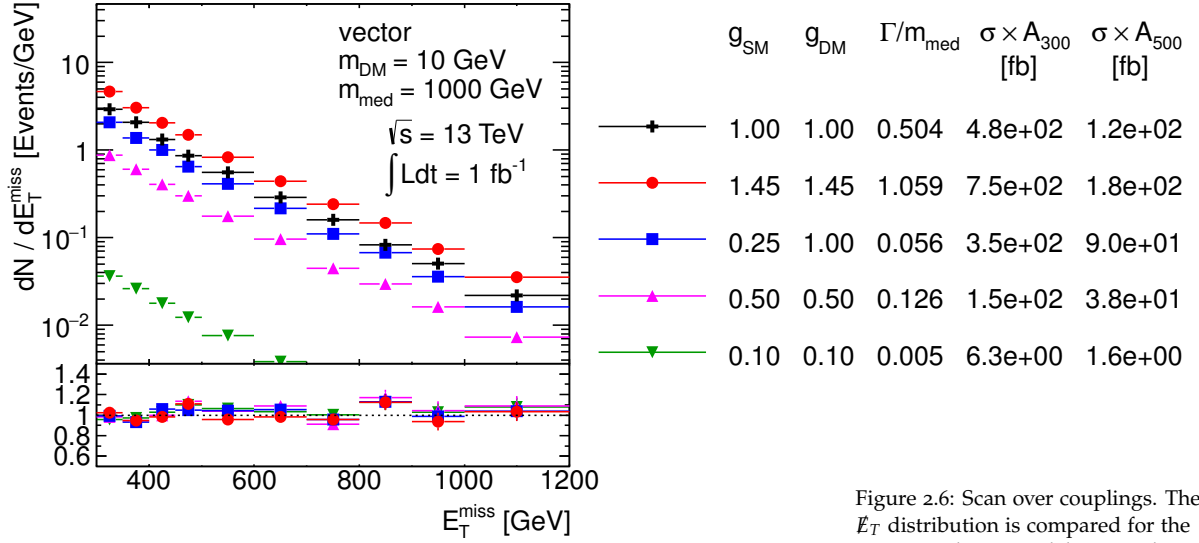

Figure 2.6: Scan over couplings. The E_T distribution is compared for the vector mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

masses of the Dark Matter pair, $m_{\tilde{\chi}\tilde{\chi}}$, is suppressed due to narrow Breit-Wigner peak that only probes a narrow window of parton distribution functions. For wider mediators, the low mass region is significantly enhanced by parton distribution functions at low Bjorken x , as illustrated in Fig. 2.8(a). This explains why the sample with the narrowest mediator in Fig. 2.7 is heavily suppressed in terms of production cross section and also gives different E_T shape. Furthermore, Fig. 2.7 compares the vector model with 5 TeV mediator to the D5 EFT sample and reveals that the simplified models with larger mediator widths (e.g. for couplings of 1 where $\Gamma_{\text{min}}/M_{\text{med}} \sim 0.5$) are the ones resembling the kinematics of contact interactions. This is because the production in the EFT model is always off-shell, i.e. no peak in the $m_{\tilde{\chi}\tilde{\chi}}$ distribution is present. In case of narrow width mediators, e.g. $\Gamma_{\text{min}}/M_{\text{med}} \sim 0.05$, even larger mediator masses need to be chosen in order to significantly suppress the peak in the $m_{\tilde{\chi}\tilde{\chi}}$ distribution and reproduce the kinematic shapes of an EFT model. Figure 2.8(b) verifies that the choice of 10 TeV mediator mass is sufficient to achieve that.

Since kinematic distributions are robust to changes in the specific values of coupling as long as heavy narrow mediators are generated correctly (see Appendix ?? for discussion), the choice of $g_q = g_{\text{DM}}$ is reasonable to reduce the parameter space to be scanned. There are no complications associated with small couplings, but, also, the early part of Run 2 will not be sensitive to them. The range of couplings we recommend limit the calculated width of the mediator to be near or below M_{med} .

For direct mediator searches, such as $q\bar{q} \rightarrow Z' \rightarrow q\bar{q}$, asymmetric couplings ($g_q \neq g_{\text{DM}}$) might also be considered. A scan in g_{DM} vs g_q can then be performed for a fixed mediator mass. Such searches may restrict g_q to a greater degree than g_{DM} .

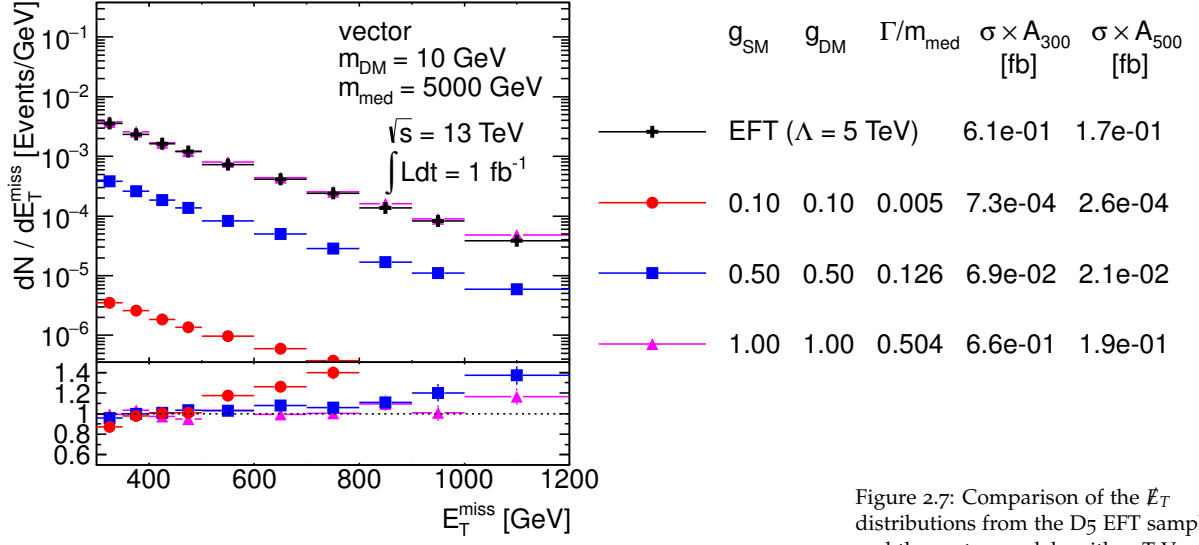

Figure 2.7: Comparison of the E_T^{miss} distributions from the D5 EFT sample and the vector models with 5 TeV heavy mediator of various widths. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

(a)

(b)

Figure 2.8: Invariant mass of the Dark Matter pair in the vector mediator samples with $m_{\text{DM}} = 10$ GeV, $M_{\text{med}} = 5$ TeV and different coupling strengths (a). Similar comparison is shown for the samples with different mediator masses considering $\Gamma_{\text{min}}/M_{\text{med}} = 0.05$ and 0.1 (b). An EFT sample is also displayed in the latter case. The distributions are normalised to unit area.

Scan over m_{DM} For a fixed mediator mass M_{med} and couplings, the Dark Matter mass falls into three regimes:

On-shell: When $M_{\text{med}} \gg 2m_{\text{DM}}$, most mediators are produced on-shell. The hardness of the ISR is set by M_{med} , and the kinematic distributions do not strongly depend on m_{DM} . This is illustrated in Fig. 2.9 for an example of $M_{\text{med}} = 1 \text{ TeV}$ $10 \text{ GeV} < m_{\text{DM}} < 300 \text{ GeV}$. The cross section decreases as the m_{DM} approaches $M_{\text{med}}/2$. A coarse binning along m_{DM} is sufficient.

Threshold: When $M_{\text{med}} \approx 2m_{\text{DM}}$, the production is resonantly enhanced, and both the cross section and kinematic distributions change more rapidly as a function of the two masses, and finer binning is needed in order to capture the changes.

Off-shell: When $M_{\text{med}} \ll 2m_{\text{DM}}$, the Dark Matter pair is produced off-shell. The mediator propagator gives an explicit suppression of $(M_{\text{med}}/Q)^4$ that suppresses hard ISR. The $m_{\text{DM}} = 1 \text{ TeV}$ case, shown in Fig. 2.9, and Figure 2.10 demonstrates that the \cancel{E}_T spectrum hardens with increasing m_{DM} , accompanied by the gradual decrease of the cross section. Due to the significant cross section suppression, it is not necessary to fully populate the parameter space. Imminent LHC searches are not expected to be sensitive to these signals.

Figure 2.9: Scan over Dark Matter mass. The \cancel{E}_T distribution is compared for the vector mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $\cancel{E}_T > 300 \text{ GeV}$ and $\cancel{E}_T > 500 \text{ GeV}$ cut, respectively.

Scan over the mediator mass Changing the mediator mass for fixed Dark Matter mass and couplings leads to significant differences in cross section and shapes of the kinematic variables for on-shell production, as shown in Fig. 2.11. As expected, higher mediator

Figure 2.10: Scan over Dark Matter mass. The E_T distribution is compared for the vector mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

masses lead to harder E_T spectra. On the other hand, the E_T shapes are similar in the off-shell Dark Matter production regime. This is illustrated in Fig. 2.12. Therefore, a coarse binning in M_{med} is sufficient in the off-shell regime.

Proposed parameter grid The final step in proposing a parameter grid is to evaluate the sensitivity of Run-2 LHC data with respect to rate and/or kinematics. The parameter scan focuses on two important regions, the light mediator region and the heavy mediator limit to reproduce the EFT limit, and takes into account the projected sensitivities for the mono-jet analysis.

Considering simplified models also allows to discuss constraints from different search channels. In the case of the s -channel exchange, the results from the mono-jet final states, where the mediator decays to a DM pair, one can also take into account dijet constraints on the processes where the mediator decays back to Standard Model particles. The importance of the dijet results depend on the magnitude of the coupling g_q . We recommend to keep the two channels rather independent by choosing $g_q = 0.25$ and $g_{\text{DM}} = 1$, based on the findings given in Ref. [CKM⁺15]. Furthermore, it is also important to mention this choice leads to $\Gamma_{\text{min}}/M_{\text{med}} \lesssim 0.06$. Note that the usual choice of $g_q = g_{\text{DM}} = 1$ used in literature leads to $\Gamma_{\text{min}}/M_{\text{med}} \sim 0.5$, which makes the applicability of the narrow with approximation questionable.

Projected sensitivities for a 14 TeV mono-jet analysis are available from ATLAS [ATL14d]. The expected upper limit at 95% confidence level on the product of cross section, acceptance and efficiency, $\sigma \times A \times \epsilon$, in the final Run-1 ATLAS mono-jet anal-

Figure 2.12: Scan over mediator mass. The E_T distribution is compared for the vector mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

ysis [ATL15d] is 51 fb and 7.2 fb for $E_T > 300$ GeV and $E_T > 500$ GeV, respectively. ATLAS estimates a factor of two increase in sensitivity with the 2015 data. Given that cross section for V +jets processes increases by roughly a factor 2 when going from $\sqrt{s} = 8$ TeV to 13 TeV, similar fiducial cross section limits can be expected with the first Run-2 data as from the final Run-1 analysis. The generator level cross section times the acceptance at $E_T > 500$ GeV for the model with couplings $g_q = 0.25$ and $g_{DM} = 1$, a light Dark Matter particle of $m_{DM} = 10$ GeV and a $M_{med} = 1$ TeV vector mediator is at the order of 100 fb, i.e. the early Run-2 mono-jet analysis is going to be sensitive to heavier mediators than this. The value of $\sigma \times A$ at $E_T > 500$ GeV for 5 TeV vector mediator is at the order of 0.1 fb, therefore this model lies beyond the reach of the LHC in the early Run 2. However, models with high enough mediators are still useful to reproduce the EFT result.

Following these arguments, M_{med} grid points are chosen, roughly equidistant in a logarithmic scale: 10 GeV, 20 GeV, 50 GeV, 100 GeV, 200 GeV, 300 GeV, 500 GeV, 1000 GeV and 2000 GeV. In the threshold regime $M_{med} = 2m_{DM}$, the m_{DM} grid points are taken at approximately $M_{med}/2$, namely: 10 GeV, 50 GeV, 150 GeV, 500 GeV and 1000 GeV. Points on the on-shell diagonal are always chosen to be 5 GeV away from the threshold, to avoid numerical instabilities in the event generation. The detailed studies of the impact of the parameter changes on the cross section and kinematic distributions presented earlier in this section support removing some of the grid points and relying on interpolation. The optimized grids proposed for the vector and axial-vector mediators are given in Table. 2.1. One point at very high mediator mass (10 TeV) is added for each of the DM masses scanned, to aid the reinterpretation of results in terms of contact interaction operators (EFTs), as discussed in Section 5.2.

Table 2.1: Simplified model benchmarks for s -channel simplified models (spin-1 mediators decaying to Dirac DM fermions in the V and A case, taking the minimum width for $g_q = 0.25$ and $g_{DM} = 1$)

The presentation of the results in the g_q - g_{DM} plane for fixed masses benefits from cross section scaling and is discussed in Section 2.5.

2.1.3 Additional considerations for $V+E_T$ signatures

All models detailed in this Section are applicable to signatures where a photon, a W boson, a Z boson or a Higgs boson is radiated from the initial state partons instead of a gluon. The experimental signature is identified as $V+E_T$ and it has been sought by ATLAS

and CMS in Refs. [CMS14b, ATL15c, CMS15c, ATL14c, ATL14a, ATL14b]. This signature is also produced by the models described in Section 3.

Monojet searches are generally more sensitive with respect to final states including bosons, due to the much larger rates of signal events featuring quark or gluon radiation with respect to radiation of bosons [ZBW13], in combination with the low branching ratios if leptons from boson decays are required in the final state. The rates for the Higgs boson radiation is too low for these models to be considered a viable benchmark [CDM⁺14]. However, the presence of photons, leptons from W and Z decays, and W or Z bosons decaying hadronically allow backgrounds to be rejected more effectively, making $Z/\gamma/W + \cancel{E}_T$ searches still worth comparing with searches in the jet+ \cancel{E}_T final state.

In the case of a spin-1 mediator, an example Feynman diagram for these processes can be constructed by taking Fig. 2.1 and replacing the gluon with γ, W or Z .

When the initial state radiation is a W^\pm boson, Run 1 searches have considered three benchmark cases adapted from the vector interaction in Ref. [BT13], distinguished by ξ , the strength of the d quark coupling relative the u quark coupling:

$\xi = 0$: Mediator couples to up-type or down-type quarks, but not both;

$\xi = 1$: Mediator couples to up-type and down-type quarks with same strength;

$\xi = -1$: Mediator couples to up-type and down-type quarks with same strength, but opposite sign.

Contemplation of $\xi = -1$ heightened interest in searches for spin-1 mediators with W^\pm bosons in the final state. This choice enhances the cross-section significantly above the other choices and hardens the distribution of missing transverse energy used in the searches. The sensitivity of the $W + \cancel{E}_T$ search then surpasses that of the jet+ \cancel{E}_T search. However, the situation $\xi = -1$ does not appear in an $SU(2)$ -gauge-invariant simplified model.² The simplified model with a vector mediator exchanged in the s -channel model is still viable when $\xi = 1$. Ref. [BCD⁺15] discusses the viability of departures $\xi < 1$ from both gauge-invariance and experimental points of view. An example of a model that arranges different effective DM couplings to u_L and d_L is detailed in Appendix A.

As in the case of the jet+ \cancel{E}_T models, the width does not have a significant impact on the kinematic distributions relevant for those searches. An example of the particle-level analysis acceptance using the generator-level cuts from Ref. [ATL15c] for the photon+ \cancel{E}_T analysis, but raising the photon p_T cut to 150 GeV, is shown in Figure 2.2, comparing a width that is set to $\Gamma = M_{med}/3$ to the minimal width (the ratio between the two widths ranges from 1.05 to 1.5 with increasing mediator masses).

² It is well-known that the diagrams in which the W couples to u and \bar{d} have opposite sign. This is what gives rise to the “helicity zero” in $u\bar{d} \rightarrow Wg$. The relative sign is set by $SU(2)$ and the statement that the mediator is an $SU(2)$ singlet. We can increase the cross section by changing the sign, but to do so we have to give the mediator some $SU(2)$ quantum number, making it, and the associated χ , visible.

Acceptance ratio for $\Gamma = \Gamma_{\min}$ vs $\Gamma = M_{\text{med}}/3$				
	m_{DM}/GeV			
$M_{\text{med}}/\text{GeV}$	10	50	200	400
50	0.96	0.99		0.95
100	0.97			
300	1.00	1.02		
600			0.96	
1000	1.01	1.02	1.03	
3000	1.02	1.03		1.01

Table 2.2: Analysis acceptance ratios for the photon+ \cancel{E}_T analysis when varying the mediator width, in the case of a vector mediator exchanged in the s -channel

Examples of relevant kinematic distributions for selected benchmark points are shown in Fig. 2.13. Leading-order cross-sections for the chosen benchmark points are shown in Appendix A.

(a) Missing transverse momentum distribution for the photon+ \cancel{E}_T final state, for different mediator mass choices, for $m_{\text{DM}}=10$ GeV.

(b) Leading photon transverse momentum distribution for the photon+ \cancel{E}_T final state, for different DM mass choices, with $M_{\text{med}}=1$ TeV.

(c) Missing transverse momentum distribution for the leptonic $Z+\cancel{E}_T$ final state, for different mediator mass choices, for $m_{\text{DM}}=15$ GeV

(d) Missing transverse momentum distribution for the hadronic $W+\cancel{E}_T$ final state.

Figure 2.13: Kinematic distributions relevant for searches with W, Z and photons in the final state, for the simplified model with a vector mediator exchanged in the s -channel.

In addition, for the vector models considered, initial and final state radiation of a Z' can occur which can appear as a narrow jet if

it decays hadronically and may not be distinguishable from a QCD jet, thus accounting for some fraction of the monojet signal. The ISR and FSR of Z' becomes more important at large values of the couplings [BBL15].

2.2 Scalar and pseudoscalar mediator, s -channel exchange

Figure 2.14: One-loop diagrams of processes exchanging a scalar (S) or pseudoscalar (P) mediator, leading to a mono-jet signature.

In this section, we consider a parallel situation to the vector and axial-vector mediators in the previous sections: a real scalar or a pseudoscalar where the associated scalar is decoupled at higher energies³. This section is largely based on Refs. [BFG15, HKSW15] which contain a thorough discussion of these models.

Assuming MFV, spin-0 resonances behave in a similar fashion as the SM Higgs boson. Relative to the vector and axial-vector models discussed above, the scalar models are distinguished by the special consequences of the MFV assumption: the very narrow width of the mediator and its extreme sensitivity to which decays are kinematically available, and the loop-induced coupling to gluons. The interaction Lagrangians are

$$\mathcal{L}_\phi = g_{\text{DM}} \phi \bar{\chi} \chi + \frac{\phi}{\sqrt{2}} \sum_i \left(g_u y_i^u \bar{u}_i u_i + g_d y_i^d \bar{d}_i d_i + g_\ell y_i^\ell \bar{\ell}_i \ell_i \right), \quad (2.6)$$

$$\mathcal{L}_a = i g_{\text{DM}} a \bar{\chi} \gamma_5 \chi + \frac{ia}{\sqrt{2}} \sum_i \left(g_u y_i^u \bar{u}_i \gamma_5 u_i + g_d y_i^d \bar{d}_i \gamma_5 d_i + g_\ell y_i^\ell \bar{\ell}_i \gamma_5 \ell_i \right). \quad (2.7)$$

where ϕ and a are respectively the scalar and pseudoscalar mediators, and the Yukawa couplings y_i^f are normalized to the Higgs vev as $y_i^f = \sqrt{2} m_i^f / v$.

The couplings to fermions are proportional to the SM Higgs couplings, yet one is still allowed to adjust an overall strength of the coupling to charged leptons and the relative couplings of u - and d -type quarks. As in the preceding sections, for the sake of simplicity and straightforward comparison, we reduce the couplings to the SM fermions to a single universal parameter $g_q \equiv g_u = g_d = g_\ell$. Unlike the vector and axial-vector models, the scalar mediators are allowed to couple to leptons.⁴

³ This assumption does not hold in a UV-complete model where the two components of the complex scalar mediator would be approximately degenerate. The complex scalar case could be studied separately in the case of heavy flavor final states given the sufficiently different kinematics.

⁴ This contribution plays no role for most of the parameter space considered. The choice to allow lepton couplings follows Refs. [BFG15, HKSW15].

The relative discovery and exclusion power of each search can be compared in this framework. However, we again emphasize the importance of searching the full set of allowed channels in case violations of these simplifying assumptions lead to significant modifications of the decay rates that unexpectedly favor different channels than the mix obtained under our assumptions. The coupling g_{DM} parameterizes the entire dependence on the structure between the mediator and the dark sector.

Given these simplifications, the minimal set of parameters under consideration is

$$\left\{ m_{\text{DM}}, m_{\phi/a} = M_{\text{med}}, g_{\text{DM}}, g_{\text{q}} \right\}. \quad (2.8)$$

Fig. 2.14 shows the one-loop diagrams producing a jet+X signature. The full calculation of the top loop is available at LO for DM pair production in association with one parton.

The minimal mediator width is given by

$$\begin{aligned} \Gamma_{\phi,a} = & \sum_f N_c \frac{y_f^2 g_q^2 m_{\phi,a}}{16\pi} \left(1 - \frac{4m_f^2}{m_{\phi,a}^2} \right)^{x/2} + \frac{g_{\text{DM}}^2 m_{\phi,a}}{8\pi} \left(1 - \frac{4m_{\text{DM}}^2}{m_{\phi,a}^2} \right)^{x/2} \\ & + \frac{\alpha_s^2 y_t^2 g_q^2 m_{\phi,a}^3}{32\pi^3 v^2} \left| f_{\phi,a} \left(\frac{4m_t^2}{m_{\phi,a}^2} \right) \right|^2 \end{aligned} \quad (2.9)$$

where $x = 3$ for scalars and $x = 1$ for pseudoscalars. The loop integrals are

$$f_{\phi}(\tau) = \tau \left[1 + (1 - \tau) \arctan^2 \left(\frac{1}{\sqrt{\tau - 1}} \right) \right], \quad (2.10)$$

$$f_a(\tau) = \tau \arctan^2 \left(\frac{1}{\sqrt{\tau - 1}} \right) \quad (2.11)$$

for $\tau < 1$, where $\tau = 4m_t^2/m_{\phi,a}^2$, and, for $\tau > 1$,

$$f_{\phi}(\tau) = \tau \left[1 + (1 - \tau) \left(-\frac{1}{4} \left(\log \frac{1 + \sqrt{1 - \tau}}{1 - \sqrt{1 - \tau}} + i\pi \right)^2 \right) \right], \quad (2.12)$$

$$f_a(\tau) = \tau \left(-\frac{1}{4} \left(\log \frac{1 + \sqrt{1 - \tau}}{1 - \sqrt{1 - \tau}} + i\pi \right)^2 \right). \quad (2.13)$$

The minimal widths for scalar and pseudo-scalar mediators with $g_{\text{q}} = g_{\text{DM}} = 1$ are shown in Fig. 2.15, illustrating the effect of choosing the SM Higgs-like Yukawa couplings for the SM fermions. For the mediator mass above twice the top quark mass m_t , the minimal width receives the dominant contribution from the top quark. For lighter mediator masses, Dark Matter dominates as the couplings to lighter quarks are Yukawa suppressed.

It can be seen in Fig. 2.16 that the kinematics for the scalar and pseudoscalar models coincides when considering the diagrams in Fig. 2.14. For this reason, we recommend to generate only one of

Figure 2.15: Minimal width as a function of mediator mass for scalar and pseudo-scalar mediator assuming couplings of 1. The total width is shown as solid lines for Dark Matter masses of $m_{\text{DM}} = 10 \text{ GeV}, 30 \text{ GeV}, 100 \text{ GeV}$ and 300 GeV in black, red, brown and green, respectively. The individual contributions from Dark Matter are indicated by dotted lines with the same colors. The contribution from all quarks but top is shown as magenta dotted line and the contribution from top quarks only is illustrated by the dotted blue line. The dotted beige line shows the contribution from the coupling to gluons. The dotted black line shows the extreme case $\Gamma_{\min} = M_{\text{med}}$.

the two models. No preference is given between the two models as they have the same kinematics, although it is worth noting that the pseudo-scalar model has been used for a Dark Matter interpretation of the DAMA signal and of the galactic center excess [ADNP15]. Like in the case of the vector and axial-vector models described in Section 2.1.1, the differences between the cross sections for the scalar and pseudo-scalar samples with the same m_{DM} and M_{med} are increasing with the Dark Matter mass for fixed mediator mass. The pseudo-scalar model gives larger cross sections. Also note the increasing differences between the minimal widths close to the $2m_{\text{DM}} = M_{\text{med}}$ threshold.

Figure 2.16: Comparison of the E_T^{miss} distributions for the scalar and pseudoscalar models for different $M_{\text{med}} = 300$ GeV and different Dark Matter masses. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

2.2.1 Parameter scan

Similarly as in the case of the vector and axial-vector couplings of spin-1 mediators, scans in the parameter space are performed also for the scalar and pseudo-scalar couplings of the spin-0 mediators in order to decide on the optimized parameter grid for the presentation of Run-2 results. Figures 2.17- 2.21 show the scans over the couplings, Dark Matter mass and mediator mass and the same conclusions apply as in Section 2.1.

A scan over the mediator mass is shown in Fig. 2.21 where $M_{\text{med}} = 300$ GeV and 500 GeV are chosen to be below and above $2m_t$. The off-shell Dark Matter production regime is assumed by taking an extreme limit ($m_{\text{DM}} = 1$ TeV) in order to study solely the effects of the couplings to quarks. No differences in the kinematic distributions are observed and also the cross sections remain similar in this case. No significant changes appear for mediator masses around the $2m_t$ threshold.

Figure 2.17: Scan over couplings. The E_T distribution is compared for the scalar mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $E_T > 300$ GeV and $E_T > 500$ GeV cut, respectively.

Figure 2.21: Scan over mediator mass. The \cancel{E}_T distribution is compared for the scalar mediator models using the parameters as indicated. Ratios of the normalized distributions with respect to the first one are shown. A_{300} and A_{500} in the table denote the acceptance of the $\cancel{E}_T > 300$ GeV and $\cancel{E}_T > 500$ GeV cut, respectively.

The optimized parameter grid in the $M_{\text{med}}-m_{\text{DM}}$ plane for scalar and pseudo-scalar mediators is motivated by similar arguments as in the previous section. Therefore, a similar pattern is followed here, taking again $g_q = 0.25$ and $g_{\text{DM}} = 1$. Only the sensitivity to the highest mediator masses has to be re-evaluated. The generator level cross section times the acceptance at $\cancel{E}_T > 500$ GeV for the model with couplings $g_q = g_{\text{DM}} = 1$, light Dark Matter of $m_{\text{DM}} = 10$ GeV and a $M_{\text{med}} = 500$ GeV scalar mediator is at the order of 10 fb, i.e. just at the edge of the early Run-2 sensitivity. Increasing the mediator mass to 1 TeV pushes the product $\sigma \times A$ down to approximately 0.1 fb, below the LHC sensitivity. Therefore, we choose to remove the 2 TeV mediator mass from the grid and present the final grid with 33 mass points only, as shown in Tab. 2.3. One point at very high mediator mass (10 TeV) is added for each of the DM masses scanned, to aid the reinterpretation of results in terms of contact interaction operators (EFTs).

m_{DM} (GeV)	M_{med} (GeV)								
1	10	20	50	100	200	300	500	1000	10000
10	10	15	50	100					10000
50	10		50	95	200	300			10000
150	10				200	295	500	1000	10000
500	10						500	995	10000
1000	10							1000	10000

Table 2.3: Simplified model benchmarks for s -channel simplified models (spin-0 mediators decaying to Dirac DM fermions in the scalar and pseudoscalar case, taking the minimum width for $g_q = 0.25$ and $g_{\text{DM}} = 1$)

2.2.2 Additional considerations for $V + \cancel{E}_T$ signatures

The discussion of parameters for the model with a color-singlet, spin-0 mediator parallels that in Section 2.

Even though the sensitivity of mono-boson searches to this model is low and it may not be in reach of early LHC searches, we

recommend to generate this model for W, Z and photon searches in order to reproduce the kinematics of contact interaction operators that are further described in Section 3.2.1, for later reinterpretation.

2.2.3 Additional considerations for $t\bar{t}$ and $b\bar{b}+\cancel{E}_T$ signatures

With the MFV assumption, the top and possibly bottom quark can play a primary role in the phenomenology. The model predicts not only the monojet process described in Section 2.2, but also production of dark matter in association with top (or bottom) pairs, as illustrated in Fig. 2.22. Dedicated searches including jets from heavy flavor quarks in the final state can be designed for this signature. Another class of simplified models, which includes a Dark Matter interpretation among many others, and yields a single top quark in the final state, is detailed in Appendix A.1.

Figure 2.22: Representative Feynman diagram showing the pair production of dark matter particles in association with $t\bar{t}$ (or $b\bar{b}$).

In some theoretically motivated scenario (e.g. for high $\tan\beta$ in 2HDM in the pMSSM), spin-0 mediators might couple more strongly to down generation quarks. This assumption motivates the study of final states involving b -quarks as a complementary search to the $t\bar{t}$ +DM models, to directly probe the b -quark coupling. In addition to the example illustrated in Fig. 2.22, an example of such a model can be found in Ref. [BFG15] and can be obtained by replacing top quarks with b quarks in Fig. 2.22. Note that, because of the kinematics features of b quark production relative to heavy t quark production, a $b\bar{b}$ +DM final state may only yield one experimentally visible b quark, leading to a mono- b signature in a model that conserves b flavor.

The parameter scan for the dedicated $t\bar{t}+\cancel{E}_T$ searches has been studied in detail to target the production mechanism of DM associated with heavy flavor quarks, still sharing many details of the scan for the scalar model with a gluon radiation. The benchmark points scanning the model parameters have been selected to ensure that the kinematic features of the parameter space are sufficiently represented. Detailed studies were performed to identify points in the $m_{\text{DM}}, m_{\phi,a}, g_{\text{DM}}, g_q$ (and $\Gamma_{\phi,a}$) parameter space that differ significantly from each other in terms of expected detector acceptance. Because missing transverse momentum is the key observable for searches, the mediator p_T spectra is taken to represent the main kinematics of a model. Another consideration in determining the set of benchmarks is to focus on the parameter space where we ex-

pect the searches to be sensitive during the 2015 LHC run. Based on a projected integrated luminosity of 30 fb^{-1} expected for 2015, we disregard model points with a cross section times branching ratio smaller than 0.1 fb , corresponding to a minimum of one expected event assuming a 0.1% signal efficiency.

The kinematics is most dependent on the masses m_{DM} and $m_{\phi,a}$. Figure 2.23 and 2.24 show typical dependencies for scalar and pseudoscalar couplings respectively. Typically, the mediator p_T spectrum broadens with larger $m_{\phi,a}$. The kinematics are also different between on-shell ($M_{\text{med}} > 2m_{\text{DM}}$) and off-shell ($M_{\text{med}} < 2m_{\text{DM}}$) mediators as discussed in Section 2.2. Furthermore, the kinematic differences in the E_T spectrum between scalar and pseudoscalar are larger for light mediator masses with respect to heavier mediators. It is therefore important to choose benchmark points covering on-shell and off-shell mediators with sufficient granularity, including the transition region between on-shell and off-shell mediators.

Figure 2.23: Example of the dependence of the kinematics on the scalar mediator mass. The Dark Matter mass is fixed to be $m_{\text{DM}} = 1 \text{ GeV}$.

Figure 2.24: Example of the dependence of the kinematics on the pseudoscalar mediator mass. The Dark Matter mass is fixed to be $m_{\text{DM}} = 1 \text{ GeV}$.

Typically only weak dependencies on couplings are observed (see Fig 2.25) where the variation with width of the integral over parton distributions is unimportant. As shown in Section 2.1.2, for couplings $\sim O(1)$ the width is large enough that the p_T of the mediator is determined mainly by the PDF.

At large mediator masses (~ 1.5 TeV) or very small couplings ($\sim 10^{-2}$), width effects are significant, but these regimes have production cross sections that are too small to be relevant for 30 fb^{-1} and are not studied here. However, with the full Run 2 dataset, such models may be within reach.

Figure 2.25: Study of the dependence of kinematics on the width of a scalar mediator. The width is increased up to four times the minimal width for each mediator and dark matter mass combination.

Another case where the width can impact the kinematics is when $m_{\phi,a}$ is slightly larger than $2m_\chi$. Here, the width determines the relative contribution between on-shell and off-shell mediators. An example is given in Fig. 2.26. As the minimal width choice pursued in this document is the most conservative one, this effect can be neglected in order to reduce the number of benchmark points to be generated.

The points for the parameter scan chosen for this model are listed in Table 2.3, chosen to be harmonized with those for other analyses employing the same scalar model as benchmark. Based on the sensitivity considerations above, DM masses are only simulated up to 500 GeV (but the 5 TeV mediator point is retained) leading to a total of 24 benchmark points. However for these searches we recommend to generate scalar and pseudoscalar models separately, as the kinematics differs due to the different coupling of the mediator to the final state top quarks in the two cases, as shown in Figs. 2.23 and 2.24.

Similar studies were performed in the $b\bar{b}$ case. It was found that they show the same weak dependence of the kinematics of the event on the mediator width. The same benchmark parameters of the $t\bar{t}$ case could then be chosen.

Figure 2.26: Dependence of the kinematics on the width of a scalar mediator. The width is increased up to the mediator mass. Choices of mediator and dark matter masses such that $m_{\phi,d}$ is slightly larger than $2m_\chi$ is the only case that shows a sizeable variation of the kinematics as a function of the width.

2.3 Colored scalar mediator, t -channel exchange

Note from the organizers: we've recently uncovered discrepancies in the two models used in the t -channel section. This will require further changes to this section that will be circulated separately in the next few days.

The preceding sections address models with a Dirac fermion coupled to the SM through exchange of a neutral spin-0 or spin-1 particle in an s -channel process. A t -channel process may couple the SM and DM directly, leading to a different phenomenology. For completeness, we examine a model where χ is a Standard Model (SM) singlet, a Dirac fermion; the mediating particle, labeled ϕ , is charged and colored; and the SM particle is a quark. Such models have been studied in Refs. [AWZ14, PVZ14, BB13, DNRT13, CEHL14, BDG⁺12]. However, this model has not been studied extensively in this forum.

Following the example of Ref. [PVZ14], the interaction Lagrangian is written as

$$\mathcal{L}_{\text{int}} = g \sum_{i=1,2} (\phi_{(i),L} \bar{Q}_{(i),L} + \phi_{(i),u,R} \bar{u}_{(i),R} + \phi_{(i),d,R} \bar{d}_{(i),R}) \chi \quad (2.14)$$

where $Q_{(i),L}$, $u_{(i),R}$ and $d_{(i),R}$ are the SM quarks of the i -th generation and $\phi_{(i),L}$, $\phi_{(i),u,R}$ and $\phi_{(i),d,R}$ are the corresponding mediators, which (unlike the s -channel mediators) must be heavier than χ . These mediators have SM gauge representations under $(SU(3), SU(2))_Y$ of $(3, 2)_{-1/6}$, $(3, 1)_{2/3}$ and $(3, 1)_{-1/3}$ respectively. Variations of the model previously studied in the literature include coupling to the left-handed quarks only [CEHL14, BDSJ⁺14], to the $\phi_{(i),u,R}$ [DNRT13] or $\phi_{(i),d,R}$ [PVZ14, A⁺14a], or some combination [BB13, AWZ14].

As for the s -channel models, we assume Minimal Flavor Violation (MFV), setting the mediator masses for each flavor equal; the

same logic also applies to the couplings g . The free parameters are then

$$\{m_{\text{DM}}, M_{\phi}, g\}. \quad (2.15)$$

The minimal width of each mediator is expressed, using the example of decay to an up quark, as

$$\begin{aligned} \Gamma(\phi_{(i)} \rightarrow \bar{u}_{(i)}\chi) &= \frac{g_{(i)}^2}{16\pi M_{\phi_{(i)}}^3} (M_{\phi_{(i)}}^2 - m_{u_{(i)}}^2 - m_{\text{DM}}^2) \\ &\times \sqrt{(M_{\phi_{(i)}}^2 - (m_{u_{(i)}} + m_{\text{DM}})^2)(M_{\phi_{(i)}}^2 - (m_{u_{(i)}} - m_{\text{DM}})^2)}, \end{aligned} \quad (2.16)$$

which reduces to

$$\frac{g_{(i)}^2 M_{\phi_{(i)}}}{16\pi} \left(1 - \frac{m_{\text{DM}}^2}{M_{\phi_{(i)}}^2}\right)^2 \quad (2.17)$$

in the limit $M_{\phi_{(i)}}, m_{\text{DM}} \gg m_{u_{(i)}}$.

The leading-order processes involved in \cancel{E}_T +jet production are shown in Fig. 2.27. Note that the generation index i for $\phi_{(i)}$ is linked to the incoming fermion(s), and it runs on all three quark generations due to the MFV assumption. However, if the coupling g includes a Yukawa coupling proportional to the quark mass, and g is sufficiently large, LHC searches will still be sensitive to this model, as explained in Section 2.3.3.

This model can also give a signal in the \cancel{E}_T + di-jet channel when, for example, the χ is exchanged in the t -channel and the resulting ϕ pair each decay to a jet + χ . Fig. 2.28 shows the leading order diagrams. Except for the gg induced process, di-jet production through the third-generation mediator $\phi_{(3),u}$ is not possible, and production through $\phi_{(3),d}$ is again suppressed. The diagram involving the t -channel exchange of χ is strongly dependent upon the Dirac fermion assumption. For a Majorana fermion, $q\bar{q}$, $\bar{q}\bar{q}$, and qq production would be possible with the latter having a pronounced enhancement at the LHC.

This model is similar to the simplified model considered in SUSY searches, implemented as the MSSM with only light squarks and a neutralino, except for two distinct points: the χ is a Dirac fermion and the coupling g is not limited to be weak scale ($g \ll 1$). In the MSSM, most of these processes are sub-dominant, even if resonantly enhanced, because the production is proportional to weak couplings. In the more general theories considered here, g is free to take on large values of order 1 or more, and thus diagrams neglected in MSSM simulation can occur at a much higher rate here. While constraints from SUSY jets+ \cancel{E}_T analyses on MSSM models can be recast to apply to the specific model in this report, DM searches should also directly test their sensitivity to the MSSM benchmark models.

Figure 2.27: Leading order mono-jet t -channel processes, adapted from [PVZ14].

Figure 2.28: Leading order two-jet t -channel processes, adapted from [PVZ14].

2.3.1 *Parameter scan*

Ref. [PVZ14] studies the parameter space and obtains bounds on this model from LHC Run 1 mono-jet and dijets+ \cancel{E}_T data. The Forum did not exhaustively compare the kinematic distributions of this model as was done in the s -channel case. While this means the recommendations below should be taken with more caution, the model is plausible and distinctive, and it should be included in the design of LHC searches.

As in the s -channel models, scans should be performed over m_{DM} and M_ϕ . The viable ranges of both parameters nearly coincide with the scan proposed for the s -channel; for simplicity we recommend adopting the s -channel mono-jet grid. In contrast to the s -channel case, the bounds one obtains from $\cancel{E}_T + X$ searches depend strongly on the width of the mediator, as is visible in Figs. 5 and 6 of Ref. [PVZ14], except in the heavy mediator limit ($M_\phi \approx 2 \text{ TeV}$). A scan over the width was not available for this report. Thus we recommend scanning a range of possible widths as discussed in a more-limited way for the s -channel mono-jet, spanning from the minimal width to a value approaching the particle limit (for example, $\Gamma \approx M_\phi/3$ in Ref. [PVZ14]).

2.3.2 *Additional considerations for $V + \cancel{E}_T$ signatures*

The model parameters with emission of an EW boson generally follow those in Section 2.3. even though fewer diagrams are involved. A representative Feynman diagram can be constructed by replacing a final-state gluon in Fig. 2.27 with a γ, W, Z boson. See Ref. [BDG⁺12] for a theoretical overview of this model with specific examples for the $Z + \cancel{E}_T$ final state.

Figure 2.29 shows the \cancel{E}_T distribution for the hadronic $Z + \cancel{E}_T$ final state, with varying dark matter and mediator mass, before any selection. The acceptance for a series of basic analysis selections ($\cancel{E}_T > 350 \text{ GeV}$, leading jet $p_T > 40 \text{ GeV}$, minimum azimuthal angle between jet and $\cancel{E}_T > 0.4$) applied at the generator level is shown in Figure 2.30.

The discussion of the parameter scan for the t -channel model in the case of signatures including EW bosons parallels that of the monojet case.

2.3.3 *Additional considerations for signatures with b -quarks + \cancel{E}_T*

Models of bottom-flavored Dark Matter that are closely related to the t -channel mediated model from this Section have been proposed in Refs. [LKW13, ABHL14]. Here, DM couples preferentially to bottom quarks, with a decoupled third generation. We describe the b -FDM model of Ref. [ABHL14], created to explain the Galactic Center (GC) gamma-ray excess observed in data collected by the Fermi-LAT collaboration [DFH⁺14, CCW15]. This model favors couplings to third-generation quarks via Yukawa couplings,

Figure 2.29: Missing transverse momentum distribution for the hadronic $Z+\ell_T$ final state, for the simplified model with a colored scalar mediator exchanged in the t -channel.

Figure 2.30: Acceptance for the hadronic $Z+\ell_T$ final state, for the simplified model with a colored scalar mediator exchanged in the t -channel.

therefore respecting the MFV assumption.

This model produces an annihilation cross section consistent with the gamma-ray excess which can be achieved for perturbative values of the couplings, while being consistent with LHC constraints on the colored mediator. For parameters capable of explaining the anomalous gamma-ray signal in terms of Dark Matter coupling preferentially to b -quarks, the model predicts a direct detection cross section that is consistent with current constraints, but within the near future reach of Direct Detection experiments and of the upcoming LHC run.

The model contains a Dirac fermion transforming as a flavor triplet, exclusively coupling to right-handed down-type quarks. The third component of the triplet χ_b comprises the cosmological DM. Within the MFV framework, the other fermions in the flavor triplet can be made sufficiently heavy and weakly-coupled that they can be neglected in the analysis. A flavor singlet, color triplet scalar

field Φ mediates the interactions between the DM and the Standard Model quarks. The model is similar to the MSSM with a light bottom squark and neutralino, and is thus a flavor-specific example of a t -channel model. Similar top-flavored models can exist, as e.g. in Refs. [KT13, BLW14a]. In the case where the top coupling is the main DM coupling, the signal is very similar to a signal from a stop quark, since unlike the other t -channel cases there is no top in the initial state PDFs. This is the reason why it wasn't considered as an additional model. More recent literature shows that other flavor states could also contribute to LHC signals, as shown in Ref. [KKY15], but such models will have to be investigated on a longer timescale with respect to that of this Forum.

The Lagrangian considered is given by

$$-\mathcal{L} \supset g\Phi^* \tilde{\chi}_b b_R + \text{h.c.} \quad (2.18)$$

Parameter scan The nature of the model is not conducive to a simple scaling behavior that would allow us to reduce the number of points to be simulated. This is because of the interference of diagrams with QCD production of the mediator (which scale as g_s^2) with diagrams that are proportional to the coupling g in the $b + \cancel{E}_T$ and $b\bar{b} + \cancel{E}_T$ final states. Fixing the couplings also fixes the mediator width, when adopting the minimal width assumption.

A full study of the parameter scan for this model was not available for this report; thus we recommend scanning a range of possible widths as discussed in a more-limited way for the s -channel mono-jet, spanning from the minimal width to a value approaching the particle limit, e.g. $g = 0.5, 1, 2, 3$. A coupling benchmark such as $g = 1$ should be considered for each mass point since this would be a distinctive feature of this benchmark from SUSY models with sbottom squarks (see Section 2.3 for further discussion).

A scan of Dark Matter and mediator masses should be done in the on-shell region $M_\Phi > m_{\text{DM}} + m_b$, since the cross-sections in the off-shell region are too small to be probed with early LHC data, spanning from 10 to 500 GeV in m_{DM} and from 10 to 1300 GeV in M_Φ .

Figure 2.31: \cancel{E}_T (left) and jet multiplicity (right) for various DM and mediator masses and couplings normalized to the relic density observed in the early universe.

Figure 2.32: E_T (left) and jet multiplicity (right) for $m_{\text{DM}} = 35$ GeV and $M_\Phi = 500$ GeV for couplings corresponding to relic density weights and also $g = 1, 2$

2.4 Spin-2 mediator

In models with extra dimensions, the Kaluza-Klein excitations of the graviton could also serve as a mediator between the Standard Model and dark sector physics. This kind of model was not studied in the forum and is not included in the recommendations, but it and models such as Ref. [LPS14] may warrant further study on a longer timescale.

2.5 Presentation of results for reinterpretation of s -channel mediator models

The aim of the parameter grid optimization done for the s -channel models in the previous sections is to reduce the parameter space that must be simulated. We then need a procedure for populating the full parameter space by using the simulated grid points. We recommend doing this as follows:

- When the dependences on parameters are known, the cross sections and efficiencies at general points can be calculated from the grid data.
- In other cases, this information can be obtained by interpolation between the grid points. We have chosen the grid points so that the dependence is sufficiently smooth that this will be possible.

The results of the scan over the couplings presented in the previous sections indicate that there are no changes in kinematic distributions for different choices of the coupling strengths. This means that the acceptance remains the same in the whole g_q - g_{DM} plane and it is sufficient to perform the detector simulation only for one single choice of g_q, g_{DM} . The resulting truth-level selection acceptance and the detector reconstruction efficiency can then be applied to all remaining grid points in the g_q - g_{DM} plane where only the generator-level cross section needs to be known. This significantly reduces the computing time as the detector response is by far the

most CPU-intensive part of the Monte Carlo sample production. However, the number of generated samples can be reduced even further if a parameterization of the cross section dependence from one grid point to another exists. In this section, we describe the details of a cross section scaling procedure that can be used to reinterpret results for a fixed coupling for s -channel mediator models.

The propagator for the s -channel exchange is written in a Breit-Wigner form as $\frac{1}{q^2 - M_{\text{med}}^2 + iM_{\text{med}}\Gamma}$, where q is the momentum transfer calculated from the two partons entering the hard process after the initial state radiation, which is equivalent to the momentum of the Dark Matter pair⁵. The size of the momentum transfer with respect to the mediator mass allows us to classify the production in the following way:

- off-shell production when $q^2 \gg M_{\text{med}}^2$ leading to suppressed cross sections,
- on-shell production when $q^2 \sim M_{\text{med}}^2$ leading to enhanced cross sections,
- effective field theory (EFT) limit when $q^2 \ll M_{\text{med}}^2$.

All three categories can be distinguished in Fig. 5.1 showing the upper limit on the interaction scale $M^* \equiv M_{\text{med}} / \sqrt{g_q g_{\text{DM}}}$ for vector mediator. In the case of the off-shell production and the EFT limit, the first and second term in the propagator dominate, respectively, which reduces the dependence on the mediator width. Therefore, in these cases one can approximate the cross section as

$$\sigma \propto g_q^2 g_{\text{DM}}^2. \quad (2.19)$$

The on-shell production regime is the most interesting one as it gives the best chances for a discovery at the LHC given the cross section enhancement. The propagator term with the width cannot be neglected in this case and, in the narrow width approximation which requires $\Gamma \ll M_{\text{med}}$ (this is not necessarily the case in the benchmarks considered in the scans), one can integrate

$$\int \frac{ds}{(s - M_{\text{med}}^2)^2 + M_{\text{med}}^2 \Gamma^2} = \frac{\pi}{M_{\text{med}} \Gamma} \quad (2.20)$$

which further implies the cross section scaling

$$\sigma \propto \frac{g_q^2 g_{\text{DM}}^2}{\Gamma}. \quad (2.21)$$

The narrow width approximation is important here as it ensures an integration over parton distribution functions (PDFs) can be neglected. In other words, it is assumed the integrand in Eq. 2.20 is non-zero only for a small region of s , such that the PDFs can be taken to be constant in this range. By simplifying the dependence of the minimal width on the couplings as $\Gamma \sim g_q^2 + g_{\text{DM}}^2$, one can approximate this scaling rule in the extreme cases as follows

⁵ Using a running width and replacing the denominator of the propagator with $q^2 - M_{\text{med}}^2 + iQ^2 \frac{\Gamma}{M_{\text{med}}}$ should be considered in the case of wide mediators [BBB⁺89].

$$\sigma \propto \frac{g_q^2 g_{\text{DM}}^2}{g_q^2 + g_{\text{DM}}^2} \xrightarrow{g_q \ll g_{\text{DM}}} g_q^2 \quad (2.22)$$

$$\sigma \propto \frac{g_q^2 g_{\text{DM}}^2}{g_q^2 + g_{\text{DM}}^2} \xrightarrow{g_q \gg g_{\text{DM}}} g_{\text{DM}}^2. \quad (2.23)$$

However, it is important to keep in mind that this formula omits color and multiplicity factors as well as possible Yukawa suppression, and there is no simple scaling rule for how the cross section changes with the Dark Matter mass and the mediator mass, or for mediators with a large width, because PDFs matter in such cases as well. Therefore, the scaling procedure outlined above is expected to work only for fixed masses and fixed mediator width, assuming the narrow width approximation applies.

Figure 2.33 shows the minimal width over the mediator mass in the g_q - g_{DM} plane for vector and scalar mediators for $M_{\text{med}} = 100$ GeV and 1000 GeV, taking $m_{\text{DM}} = 10$ GeV. The individual colors indicate the lines of constant width, along which the cross section scaling may work for narrow mediators. The limiting case $\Gamma_{\text{min}} = M_{\text{med}}$ defines the upper values of the couplings below which the narrow width approximation can be considered and provides more stringent constraint than the perturbative limit $g_q = g_{\text{DM}} = 4\pi$. For vector and axial-vector mediators, the minimal width is predominantly defined by g_q due to the number of quark flavors and the color factor. On the contrary, both the Standard Model and Dark Matter partial width have comparable contributions in case of scalar and pseudo-scalar mediators if the top quark channel is open ($M_{\text{med}} > 2m_t$). However, mostly g_{DM} defines the minimal width for $M_{\text{med}} < 2m_t$ due to the Yukawa-suppressed light quark couplings.

The performance of the cross section scaling is demonstrated in Fig. 2.34 where two mass points $M_{\text{med}} = 100$ GeV and 1 TeV with $m_{\text{DM}} = 10$ GeV are chosen and rescaled from the starting point $g_q = g_{\text{DM}} = 1$ according to Eq. 2.21 to populate the whole g_q - g_{DM} plane. This means the width is not kept constant in this test and this is done in purpose in order to point out deviations from the scaling when the width is altered. For each mass point, the rescaled cross section is compared to the generator cross section and the ratio of the two is plotted. For the given choice of the mass points, the scaling seems to work approximately within the precision of $\sim 20\%$ in the region where $\Gamma_{\text{min}} < M_{\text{med}}$. Constant colors indicate the lines along which the cross section scaling works precisely and there is a remarkable resemblance of the patterns shown in the plots of the mediator width. To prove the scaling along the lines of constant width works, one such line is chosen in Fig. 2.35 for a scalar mediator, defined by $M_{\text{med}} = 300$ GeV, $m_{\text{DM}} = 100$ GeV, $g_q = g_{\text{DM}} = 1$, and the rescaled and generated cross sections are found to agree within 3%.

Figure 2.33: Minimal width over the mediator mass for vector (top) and scalar (bottom) mediators as a function of the individual couplings g_q and g_{DM} , assuming $M_{med} = 100$ GeV (left) and $M_{med} = 1$ TeV (right). $m_{DM} = 10$ GeV is considered in all cases. Only the cases with $\Gamma_{min} < M_{med}$ are shown.

2.5.1 Proposed parameter grid for cross-section scaling

We propose to deliver collider results in the g_q - g_{DM} plane using the following prescription, to ease reinterpretation through cross-section scaling:

- Since the shapes of kinematic quantities do not change for different couplings, use the acceptance and efficiency for the available $m_{DM} = 50$ GeV, $M_{med} = 300$ GeV, $g_q = 0.25$, $g_{DM} = 1$ grid point from the M_{med} - m_{DM} plane for the scalar and pseudo-scalar mediator. In case of the vector and axial-vector mediator, use the grid point $m_{DM} = 150$ GeV, $M_{med} = 1$ TeV, $g_q = 0.25$, $g_{DM} = 1$.
- Generate additional samples in order to get generator cross sections only. For scalar and pseudo-scalar mediator, choose $m_{DM} = 50$ GeV, $M_{med} = 300$ GeV with the following values for $g_q = g_{DM}$: 0.1, 1, 2, 3. For vector and axial vector mediator, choose $m_{DM} = 150$ GeV, $M_{med} = 1$ TeV with the following values for $g_q = g_{DM}$: 0.1, 0.25, 0.5, 0.75, 1, 1.25, 1.5. The upper values are defined by the minimal width reaching the mediator mass.
- Rescale the generator cross sections for on-shell resonance production along the lines of constant width in order to populate the whole g_q - g_{DM} plane in the region $\Gamma_{min} < M_{med}$. The scaling

To do Waiting for scalar mediator calculation of perturbativity limit from J. Alcaraz.). (??)

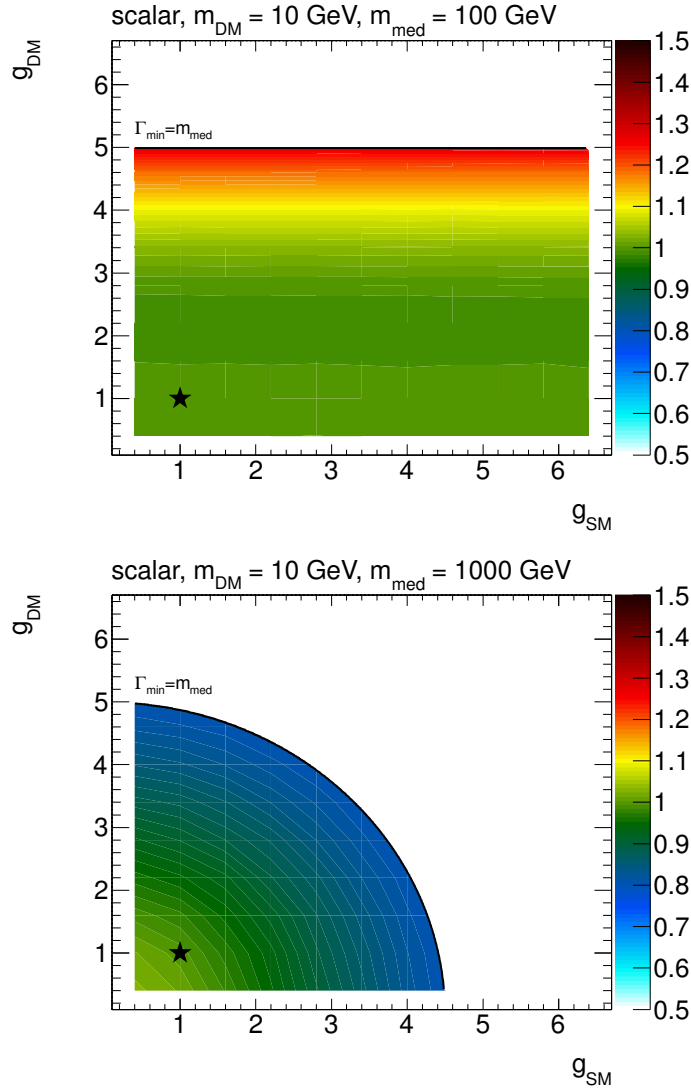

Figure 2.34: Ratio of the rescaled and generated cross sections in the g_q - g_{DM} plane. The point at $g_q = g_{DM} = 1$, taken as a reference for the rescaling, is denoted by a star symbol. Scalar model with $M_{med} = 100$ GeV (left) and 1 TeV (right) is plotted for $m_{DM} = 10$ GeV. The limiting case $\Gamma_{min} = M_{med}$ is indicated by a black line and no results are shown beyond.

Figure 2.35: Scaling along the lines of constant width. The line of constant width for $M_{\text{med}} = 300$ GeV and $m_{\text{DM}} = 100$ GeV, intercepting $g_{\text{q}} = g_{\text{DM}} = 4$ is shown on left. The generated and rescaled cross sections are compared in the middle, the corresponding ratio is shown on right.

follows from Eq. 2.21 which for the constant width implies:

$$\sigma' = \sigma \times \frac{g_q'^2 g_{DM}^2}{g_q^2 g_{DM}^2}. \quad (2.24)$$

2.5.2 Rescaling to different mediator width

In general it is also important to consider a larger mediator width than Γ_{\min} in order to accommodate additional interactions of the mediator with the visible and hidden sector particles [BFG15, HKSW15]. If the narrow width approximation applies, the cross section scaling method described above can be used to reinterpret the results presented for the minimal width, since multiplying the width by factor n is equivalent to changing the coupling strength by factor \sqrt{n} , i.e.

$$\sigma(g_q, g_{DM}, n\Gamma_{\min}(g_q, g_{DM})) \propto \frac{g_q^2 g_{DM}^2}{\Gamma_{\min}(\sqrt{n}g_q, \sqrt{n}g_{DM})}. \quad (2.25)$$

The cross section for the sample with couplings g_q and g_{DM} and modified mediator width $\Gamma = n\Gamma_{\min}$ can therefore be rescaled from a sample generated with the minimal width corresponding to the couplings scaled by \sqrt{n} as described in the following formula.

$$\sigma(g_q, g_{DM}, n\Gamma_{\min}(g_q, g_{DM})) = \frac{1}{n^2} \sigma(\sqrt{n}g_q, \sqrt{n}g_{DM}, \Gamma_{\min}(\sqrt{n}g_q, \sqrt{n}g_{DM})) \quad (2.26)$$

The advantage of doing this is in the fact that no event selection and detector response needs to be simulated since the changes in couplings do not have an effect on the shapes of kinematic distributions.

It should be noted again that this procedure is only useful when the narrow width approximation applies. Care must be taken to ensure that is the case. For example, in the vector and axial-vector cases, one quickly breaks this approximation even for small n .

2.5.3 Additional considerations for $t\bar{t}$ and $b\bar{b} + \cancel{E}_T$ signatures

The cross-section scaling considerations shown in Sec. 2.5 still apply for the reactions in the scalar and psuedoscalar models with explicit b and t quarks. Here we detail the specific studies done for the $t\bar{t}$ model.

Given that the kinematics are similar for all couplings $g \simeq 1$, we recommend to generate only samples with $g_{DM} = g_q = 1$. It follows from this that these benchmark points should be a good approximation for non-unity couplings and for $g_{DM} \neq g_q$, provided that the sample is rescaled to the appropriate cross section times branching ratio.

While the simple scaling function

$$\sigma' \times BR' = [\sigma \times BR] \times \left(\frac{g_q'}{g_q}\right)^2 \times \left(\frac{g_{DM}'}{g_{DM}}\right)^2 \times \frac{\Gamma}{\Gamma'} \quad (2.27)$$

1164 is sufficient for a limited range of coupling values (see Fig. 2.36 for
 1165 example), this scaling is only approximate (up to 20%) and relies on
 1166 the narrow width approximation, ignoring PDFs effects.

Figure 2.36: An example comparing a simple cross section scaling versus the computation from the MADGRAPH5_AMC@NLO generator, for a scalar $t\bar{t} + E_T$ model with $m_\phi = 400$ GeV, $m_{DM} = 1$ GeV and all couplings set to unity. In this example, the scaling relationship holds for Γ_ϕ/m_ϕ below 0.2, beyond which finite width effects become important and the simple scaling breaks down.

3

Specific models for signatures with EW bosons

In this Section, we consider specific models with a photon, a W boson, a Z boson or a Higgs boson in the final state ($V + \cancel{E}_T$ signature), accompanied by Dark Matter particles that either couple directly to the boson or are mediated by a new particle. The common feature of those models is that they provide different kinematic distributions with respect to the models described in Section 2.

Figure 3.1: Sketch of benchmark models including a contact interaction for $V + \cancel{E}_T$ searches, adapted from [NCC⁺14].

The models considered in this Section can be divided into two categories:

V-specific simplified models These models postulate direct couplings of new mediators to bosons, e.g. they couple the Higgs boson to a new vector or to a new scalar [CDM⁺14, BLW14b].

Models involving a SM singlet operator including a boson pair that couples to dark matter through a contact interaction Shown on the right-hand side of Figure 3.1, these models allow for a contact interaction vertex that directly couples the boson to Dark Matter [CHLR13, CNS⁺13, CHH15, BLW14b]. These models are included in this report devoted to simplified models since UV completions for most of these operators proceed through loops and are not available to date. These models provide a benchmark to motivate signal regions that are unique to searches with EW final states and would otherwise not be studied. However, we recommend to use these models as placeholders and emphasize model-independent results especially in signal regions tailored to these models. Wherever results are interpreted in terms of these operators, a truncation procedure to ensure the validity of the EFT should be employed, as detailed in the next Section (Sec. 5).

The following Sections describe the models within these categories, the parameters for each of the benchmark models chosen, the studies towards the choices of the parameters to be scanned.

3.1 Specific simplified models including EW bosons, tailored to Higgs+MET searches

Three benchmark simplified models [CDM⁺₁₄, BLW_{14b}] are recommended for Higgs+ \cancel{E}_T searches:

- A model where a vector mediator (Z'_B) is exchanged in the s-channel, radiates a Higgs boson, and decays into two DM particles (Fig. 3.2 (a)). As in Section 2.1, we conservatively omit couplings of the Z'_B to leptons.
- A model where a scalar mediator S is emitted from the Higgs boson and decays to a pair of DM particles (Fig. 3.3).
- A model where a vector Z' is produced resonantly and decays into a Higgs boson plus an intermediate heavy pseudoscalar particle A^0 , in turn decaying into two DM particles (Fig. 3.2 (b)).

Figure 3.2: Examples of Feynman diagrams leading to Higgs+ \cancel{E}_T events: (a) a model with a vector mediator (Z') coupling with DM and with the Higgs boson h , and (b) a 2HDM model with a new invisibly decaying pseudoscalar A^0 from the decay of an on-shell resonance Z' giving rise to a Higgs+ \cancel{E}_T signature.

These models are kinematically distinct from one another, as shown in the comparison of the \cancel{E}_T spectra in Fig. 3.4 for high and low masses of the pseudoscalar mediator. Figure 3.4 (a) shows the \cancel{E}_T distribution for models with high mediator masses ($m_S = 1$ TeV, $m_{Z'} = 1$ TeV, $m_{A^0} = 1$ TeV) and DM mass of either 50 (Z'_B and A^0 models) or 65 GeV (scalar mediator model). Figure 3.4 (b) shows the \cancel{E}_T distribution for models with low pseudoscalar mediator masses ($m_{Z'_B} = 100$ GeV, $m_{Z'} = 1$ TeV, $m_{A^0} = 100$ GeV) and DM mass of 1 TeV for all models.

3.1.1 \cancel{E}_T + Higgs from a baryonic Z'

The model shown in Fig. 3.2 (a) postulates a new gauge boson Z' corresponding to a new $U(1)_B$ baryon number symmetry. The stable baryonic states included in this model are the DM candidate particles. The mass of the Z' boson is acquired through a baryonic Higgs h_B , which mixes with the SM Higgs boson.

Figure 3.3: Examples of Feynman diagrams leading to Higgs+ E_T events for a model with a scalar mediator (S) coupling with DM and with the Higgs boson h .

The interactions between the Z' , the quarks and the DM are described by the following Lagrangian:

$$L = g_q \bar{q} \gamma^\mu q Z'_\mu + g_{DM} \bar{\chi} \gamma^\mu \chi Z'_\mu. \quad (3.1)$$

The quark couplings g_q are fixed to be equal to one third of the gauge coupling g_B , while the DM coupling to the Z' are proportional to the baryon number and to the gauge coupling ($g_\chi = B g_B$). No leptonic couplings of the Z' are allowed, thus evading dilepton constraints. After incorporating the mixing of the baryonic and SM Higgs bosons, this model is described by the following Lagrangian term at energies below $m_{Z'}$ ¹:

$$L_{\text{eff}} = -\frac{g_q g_{DM}}{m_{Z'}^2} \bar{q} \gamma^\mu q \bar{\chi} \gamma_\mu \chi \left(1 + \frac{g_{hZ'Z'}}{m_{Z'}^2} h \right), \quad (3.2)$$

The first term of this equation is the standard DMV model in the large $M_{Z'}$ limit. This term can lead to a monojet signature, which can be also used to constrain this model. The second term describes the interaction between the Z' and the SM Higgs boson, via the coupling $g_{hZ'Z'} = \frac{m_{Z'}^2 \sin \theta}{v_B}$, where $\sin \theta$ is the mixing angle between the SM Higgs and the baryonic Higgs h_B , and v_B is the Baryonic Higgs vacuum expectation value.

"In its most general form, this model can contribute to mono- Z signals due to the Z' mixing with the Z or photon. Note that EWSB and $U(1)_B$ breaking do not lead to this mixing at tree-level. Instead, kinetic mixing occurs between the $U(1)_Y$ and $U(1)_B$ gauge bosons due to the gauge invariant term $F_Y^{\mu\nu} F_{B\mu\nu}$. This mixing is a free parameter which we assume to be small in order to focus on the mono-Higgs signature. Mixing may also occur due to radiative corrections, however this is model dependent so we choose to ignore this here.

¹ The operator in Eqn. 3.2 is an effective one, to highlight the two main terms. The full dimension-4 simplified model is used in the model for event generation.

(a) High mediator mass

(b) Low mediator mass

Figure 3.4: Comparison of the missing transverse momentum distributions at generator level in different simplified models leading to a Higgs+ \cancel{E}_T signature. The model parameter settings are detailed in the text.

The predictions of the model depend upon the two additional parameters beyond an s -channel simplified model, namely the mixing angle between baryonic Higgs h_B and the SM-like Higgs boson $\sin \theta$ and the coupling of the mediator to SM-like Higgs boson, $g_{hZ'Z'}$. Thus, a full model is specified by:

$$\{M_{\text{med}}, m_{\text{DM}}, g_{\text{DM}}, g_q, \sin \theta, g_{hZ'Z'}\}. \quad (3.3)$$

3.1.1.1 Parameter scan

The width of the Z' mediator is calculated using all possible decays to SM particles (quarks) and to pairs of DM particles if kinematically allowed as in the DMV model.

The dependence of the missing transverse momentum (\cancel{E}_T) on the model parameters is studied by varying the parameters one at a time. The variation of parameters other than M_{med} and m_{DM} does not result in significant variations of the \cancel{E}_T spectrum, as shown in Figures 3.5. Figure 3.6 shows that for an on-shell mediator, varying m_{DM} with the other parameters fixed does not affect the \cancel{E}_T distribution, while the distribution broadens significantly in the case of an off-shell mediator. For this reason, the same grid in $M_{\text{med}}, m_{\text{DM}}$ as for the vector mediator of the jet+ \cancel{E}_T search (Table 2.1) is chosen as a starting point. The coupling $g_{hZ'Z'}$, along with g_q and g_{DM} , are subject to perturbativity bounds:

$$g_q, g_{\text{DM}} < 4\pi$$

and

$$g_{hZ'Z'} < \sqrt{4\pi} m_{Z'} \sin \theta$$

The value $g_{hZ'Z'}/m_{Z'} = 1$ is chosen as a benchmark value for the generation of Monte Carlo samples since it maximizes the cross section (as shown in the following paragraph) without violating the bounds. The mediator-DM coupling g_{DM} is fixed to 1, and the mediator-quark g_q coupling is fixed to $1/3$. The kinematic distributions do not change as a function of these parameters, so results for other values of $g_{hZ'Z'}/m_{Z'}$, g_{DM} and g_q can be obtained through rescaling by the appropriate cross sections.

Figs 3.7 and 3.8 show the kinematic distributions for the two leading jets in the $H \rightarrow \bar{b}b$ decay channel, for two values of the mediator mass and varying the DM mass.

Analyses should perform further studies, beyond those studies performed for the forum, to estimate the reach of the analysis with respect to all points in the grid and therefore decide on a smaller set of grid points to be generated.

3.1.2 \cancel{E}_T + Higgs from a scalar mediator

A real scalar singlet S coupling to DM can be introduced as a portal between SM and the dark sector through the Higgs field. The most

general scalar potential is detailed in Ref. [ORMW07], including terms that break \mathbb{Z}_2 . The \mathbb{Z}_2 symmetry, which causes the new scalar to also be a DM candidate, is not covered in this report, but follows Ref. [CDM⁺14] introducing an additional coupling to DM that breaks \mathbb{Z}_2 and leads to a new invisible decay of S . For this reason, no symmetry is broken and no new interactions arise, so there is no dependence on the vacuum expectation value of S : a shift in the field leads to a redefinition of the model couplings. The new scalar S mixes with the SM Higgs boson, and couples to DM through a Yukawa term y_χ . The relevant terms in the scalar potential are:

$$V \supset a|H|^2 S + b|H|^2 S^2 + \lambda_h |H|^4 \\ \longrightarrow \frac{1}{2}a(h+v)^2 S + \frac{1}{2}b(h+v)^2 S^2 + \frac{\lambda_h}{4}(h+v)^4, \quad (3.4)$$

where a, b are new physics couplings and λ_h is the Higgs quartic coupling.

The additional Lagrangian terms for this model are:

$$L \supset -y_\chi \bar{\chi} \chi (\cos \theta S - \sin \theta h) - \frac{m_q}{v} \bar{q} q (\cos \theta h + \sin \theta S) \quad (3.5)$$

where θ is the mixing angle between the Higgs boson and the new scalar.

Mono-Higgs signals in this second model arise through processes shown in Fig. 3.3 (a,b), or through the radiation of a Higgs boson from the t quark in the production loop, in Fig. 3.3 (c). The first two processes depend on the $h^2 S$ and $h S^2$ cubic terms in Eq. (3.4). At leading order in $\sin \theta$, these terms are:

$$V_{\text{cubic}} \approx \frac{\sin \theta}{v} (2m_h^2 + m_S^2) h^2 S + b v h S^2 + \dots \quad (3.6)$$

with a and λ_h expressed in terms of $\sin \theta$ and m_h^2 , respectively. At leading order of $\sin \theta$, the $h^2 S$ term is fixed once the mass eigenvalues m_h, m_S and mixing angle are specified. The $h S^2$ term is not fixed and remains a free parameter of the model, depending on the new physics coupling b .

This model has mono-X signatures through h/S mixing. If $m_S \gg m_h$ or $m_h \gg m_S$, this model is a case of the scalar model discussed in Section 2.2, with M_{med} equal to the lighter of the two masses.

3.1.2.1 Parameter scan

The model is described by five parameters:

1. the Yukawa coupling of heavy scalar to dark matter, g_{DM} (also referred to as y_χ)
2. the mixing angle between heavy scalar and SM-like Higgs boson, $\sin \theta$;

3. the new physics coupling, b ;
4. mass of heavy scalar, m_S , also termed M_{med} ;
5. mass of dark matter, m_{DM} ;

The mixing angle is constrained from current Higgs data to satisfy $\cos \theta = 1$ within 10% and therefore $\sin \theta \lesssim 0.4$. This provides a starting point for the parameter scan in this model: we recommend to set $\sin \theta = 0.3$.

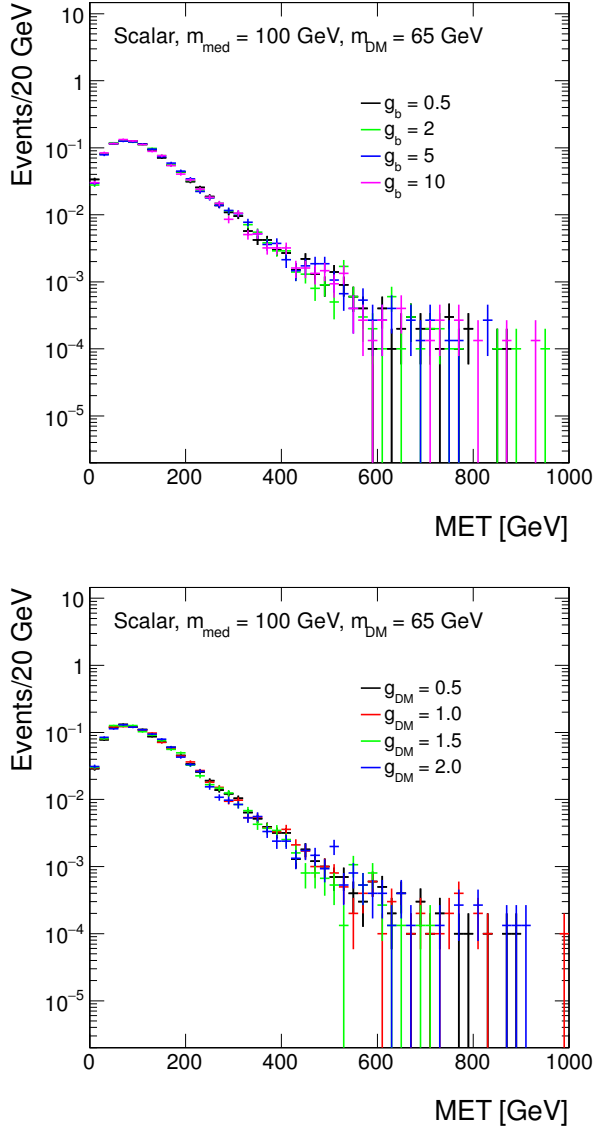

Figure 3.9: Missing transverse momentum distributions at generator level in the scalar mediator scenario, for different values of: the new physics coupling g_b (left), and the mediator-dark matter coupling g_{DM} (right).

Figure 3.10 shows that there is no dependence of the kinematics from the value of this angle, and different values can be obtained via rescaling the results for this mixing angle according to the relevant cross-section. It can also be observed from Figures 3.11 and 3.9 that the kinematics of this model follows that of the equivalent jet+ \cancel{E}_T model: only small changes are observed in the on-shell region, while the relevant distributions diverge when the mediator

is off-shell. For this reason, the same grid in $M_{\text{med}}, m_{\text{DM}}$ as for the scalar mediator of the jet+ \cancel{E}_T search (Table 2.3) is chosen as a starting point. The Yukawa coupling to DM y_{DM} is set to 1, the new physics coupling between scalar and SM Higgs $b = 3$. Results for other values can be obtained via a rescaling of the results for these parameters.

To do Estimate the sensitivity and possibly prune parameter scan. (??)

Figure 3.10: Missing transverse momentum distributions at generator level in the scalar mediator scenario: for different values of the mixing angle $\sin \theta$.

Figs. 3.12 and 3.13 show the kinematic distributions for the two leading jets in the $H \rightarrow \bar{b}b$ decay channel, for two values of the mediator mass and varying the DM mass.

3.1.3 Higgs+ \cancel{E}_T signal from 2HDM model with a Z' and a new pseudoscalar

In this simplified model [BLW14b], a new Z' resonance decays to a Higgs boson h plus a heavy pseudoscalar state A^0 in the 2HDM framework, which in turn decays to a DM pair. This model is represented in the diagram in Fig. 3.2 (b).

The motivation for coupling the dark matter to the pseudoscalar is that dark matter coupling to a Higgs or Z' boson is generically constrained by other signal channels and direct detection. A reason to consider this model is that it has different kinematics due to the on-shell Z' production, where for heavy Z' masses the \cancel{E}_T and p_T spectra are much harder. This model can satisfy electroweak precision tests and constraints from dijet resonance searches, and still give a potentially observable Higgs+ \cancel{E}_T signal.

This model comprises two doublets, where Φ_u couples to up-type quarks and Φ_d couples to down-type quarks and leptons:

$$-\mathcal{L} \supset y_u Q \tilde{\Phi}_u \bar{u} + y_d Q \Phi_d \bar{d} + y_e L \Phi_d \bar{e} + \text{h.c.} \quad (3.7)$$

After electroweak symmetry breaking, the Higgs doublets attain vacuum expectation values v_u and v_d , and in unitary gauge the

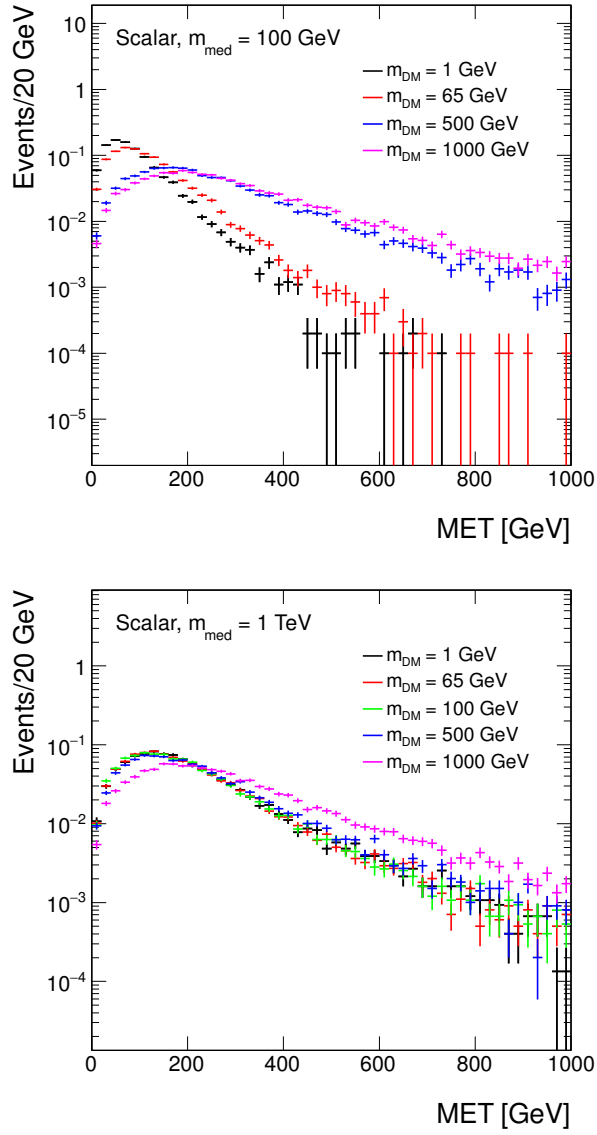

Figure 3.11: Missing transverse momentum distributions at generator level in the scalar mediator scenario: for different values of the dark matter mass m_{DM} and a mediator mass of $M_{\text{med}} = 100$ GeV (left) and $M_{\text{med}} = 1$ TeV (right).

(a) Leading b -jet transverse momentum(b) Leading b -jet pseudorapidity(c) Angular distance between the two leading b -jets

Figure 3.12: Comparison of the kinematic distributions for the two leading jets from the Higgs decay in the scalar simplified model, when fixing the new scalar mass to 100 GeV and varying the DM mass.

(a) Leading b -jet transverse momentum(b) Leading b -jet pseudorapidity(c) Angular distance between the two leading b -jets

Figure 3.13: Comparison of the kinematic distributions for the two leading jets from the Higgs decay in the scalar simplified model, when fixing the new scalar mass to 1000 GeV and varying the DM mass.

doublets are parametrized as

$$\begin{aligned}\Phi_d &= \frac{1}{\sqrt{2}} \begin{pmatrix} -\sin \beta H^+ \\ v_d - \sin \alpha h + \cos \alpha H - i \sin \beta A^0 \end{pmatrix}, \\ \Phi_u &= \frac{1}{\sqrt{2}} \begin{pmatrix} \cos \beta H^+ \\ v_u + \cos \alpha h + \sin \alpha H + i \cos \beta A^0 \end{pmatrix}\end{aligned}\quad (3.8)$$

where h, H are neutral CP-even scalars, H^\pm is a charged scalar, and A^0 is a neutral CP-odd scalar. In this framework, $\tan \beta \equiv v_u/v_d$, and α is the mixing angle that diagonalizes the $h - H$ mass squared matrix. We take $\alpha = \beta - \pi/2$, in the limit where h has SM-like couplings to fermions and gauge bosons as per Ref. [CGT13], and $\tan \beta \geq 0.3$ as implied from the perturbativity of the top Yukawa coupling. The Higgs vacuum expectation values lead to $Z - Z'$ mass mixing, with a small mixing parameter given by

$$\begin{aligned}\epsilon &\equiv \frac{1}{M_{Z'}^2 - M_Z^2} \frac{g g_z}{2 \cos \theta_w} (z_d v_d^2 + z_u v_u^2) \\ &= \frac{(M_Z^0)^2}{M_{Z'}^2 - M_Z^2} \frac{2 g_z \cos \theta_w}{g} z_u \sin^2 \beta,\end{aligned}\quad (3.9)$$

where z_i are the Z' charges of the two Higgs doublets, and g and g_z related to the mass-squared values in absence of mixing $(M_Z^0)^2 = g^2(v_d^2 + v_u^2)/(4 \cos^2 \theta_w)$ and $(M_{Z'}^0)^2 = g_z^2(z_d^2 v_d^2 + z_u^2 v_u^2 + z_\phi^2 v_\phi^2)$.

The production cross section for this model scales as $(g_z)^2$, as the decay width for this process to leading order in ϵ (Eq. 3.9) is

$$\Gamma_{Z' \rightarrow h A^0} = (g_z \cos \alpha \cos \beta)^2 \frac{|p|}{24\pi} \frac{|p|^2}{M_{Z'}^2}. \quad (3.10)$$

where the center of mass momentum for the decay products $|p| = \frac{1}{2M_{Z'}} \sqrt{(M_{Z'}^2 - (m_h + m_{A^0})^2)(M_{Z'}^2 - (m_h - m_{A^0})^2)}$.

3.1.3.1 Parameter scan

The model is described by five parameters:

- the pseudoscalar mass M_{A^0} ,
- the DM mass m_{DM} ,
- the Z' mass, $M_{Z'}$,
- $\tan \beta (\equiv v_u/v_d)$,
- the Z' coupling strength g_z .

To study the signal production and kinematic dependencies on these parameters, we produced signal samples varying each of the five parameters through MADGRAPH5_AMC@NLO for the matrix element, PYTHIA for the parton shower, and DELPHES[dF⁺14] for a parameterized detector-level simulation.

To do Steve Mrenna (?): Total width still comes from qqZ' and chichiZ' couplings? CD: what do you mean? (??)

To do What about Z' coupling to q and DM? CD: isn't this the DMV model? (??)

As seen in Fig. 3.14, variations of $\tan\beta$ does not lead to any kinematic difference and the production cross section simply scales as a function of $\tan\beta$. Hence we recommend to fix $\tan\beta$ to unity in the signal generation.

(a) E_T distribution(b) $\Delta\phi$ distance between the two b -jets

Figure 3.14: Kinematic distributions of the signal process varying $\tan\beta$, in the case of a Higgs boson decaying into two b quarks, after parameterized detector simulation: no kinematic dependence is observed

Similarly, variations of g_z do not lead to any kinematic changes. The value of g_z for a given $M_{Z'}$ and $\tan\beta$ can be set according to the maximum value allowed by electroweak global fits and dijet constraints, as described in [BLW14b]. Since this parameter does not influence the kinematics, we leave it up to individual analyses on whether they generate benchmark points only according to these external constraints.

Since the DM pair are produced as a result of the decay of A^0 , there are minimal kinematic changes when varying m_{DM} as long as $m_{\text{DM}} < M_{A^0}/2$ so that A^0 production is on-shell, as shown in Fig. 3.15 and 3.16 (before detector simulation).

We recommend to produce signal events for a fixed $g_z = 0.8$, $\tan\beta = 1$ and $m_{\text{DM}} = 100$ GeV. For these values, we scan the 2-D parameter space of $M_{Z'}$, M_{A^0} with $M_{Z'} = 600, 800, 1000, 1200, 1400$ GeV, and $M_{A^0} = 300, 400, 500, 600, 700, 800$ GeV with $M_{A^0} < M_{Z'} - m_h$, for a total of 24 points. The choice of scan is justified by the sensitivity study in [BLW14b]: the expected LHC sensitivity for Run-2 is up to $M_{Z'} \sim 1.5$ TeV. For the parameter scan, the DM mass is fixed to 100 GeV. For two $M_{Z'}$, M_{A^0} value sets, we vary the DM

Figure 3.15: Kinematic distributions of the signal process varying m_{DM} : minimal kinematic dependency on m_{DM} as expected when A^0 is produced on-shell. Plots shown for $M_{Z'} = 1000 \text{ GeV}$, $M_{A^0} = 300 \text{ GeV}$.

mass to obtain sample cross section for rescaling results. All LO cross sections for the various parameter scan points are reported in Appendix A. The parameter scan excludes the off-shell region, as the cross-sections are suppressed and the LHC would not have any sensitivity to these benchmark points in early data.

The kinematic distributions with varying $M_{Z'}$ for fixed M_{A^0} are shown in Fig. 3.17, while the dependency on M_{A^0} is shown in Fig. 3.18.

This model also allows for an additional source of Higgs plus \cancel{E}_T signal with a similar kinematics (Fig. 3.19, shown with detector simulation samples) to the signal process from the decay of $Z' \rightarrow hZ$, where the Z decays invisibly. The partial decay width for the Z' is:

$$\Gamma_{Z' \rightarrow hZ} = (g_z \cos \alpha \sin \beta)^2 \frac{|p|}{24\pi} \left(\frac{|p|^2}{M_{Z'}^2} + 3 \frac{M_Z^2}{M_{Z'}^2} \right), \quad (3.11)$$

The values for the Z' masses scanned for those samples should follow those of the previous samples, namely values of $M_{Z'} = 600, 800, 1000, 1200, 1400 \text{ GeV}$. This signal process has no M_A dependence.

THE IMPLEMENTATION OF THESE MODELS IS DISCUSSED IN APPENDIX 4.2.1.

3.2 EFT models with direct DM-boson couplings

The EFT operators considered in this section do not have a simplified model completion for Dirac fermion Dark Matter available to date. They provide kinematic distributions that are unique to mono-boson signatures, and that in most cases are not reproduced by an equivalent simplified model.²

A complete list of effective operators with direct DM/boson couplings for Dirac DM, up to dimension 7, can be found in [CHLR13, CNS⁺13, CHH15]. Higher dimensional operators, up to dimension 8, leading to Higgs+ \cancel{E}_T signatures, are mentioned in [CNS⁺13, BLW14b]. The first part of this Section outlines the main characteristics for a limited number of these models that could be considered in Run-2 searches. However, the EFT approximation made for these operators can be problematic, see Ref. [BLW14b] for discussion. For this reason, model-independent results as in Appendix B should be privileged over considering these operators as realistic benchmarks.

However, another consideration that emerged from the Forum discussion was that the EFT approach allows more model-independence when reinterpreting results, making it worth still having results available in terms of these operators. Furthermore, once simplified models are available for those operators, EFT results can be used as a limiting case for consistency checks. We devote the end of this Section to a discussion on the presentation of results from this model, including an assessment of their reliability using a conservative procedure that is only dependent on EFT parameters.

3.2.1 Dimension 5 operators

The lowest dimension benchmark operators we consider are effective dimension 5, such as the one depicted in Figure 3.20.

² Wherever this is the case, we recommend only the generation of simplified model result as the results can be rescaled and reinterpreted.

Figure 3.20: Diagram for EFT operators giving rise to a Higgs+ \cancel{E}_T signature.

Following the notation of [CNS⁺13], models from this category have a Lagrangian that includes terms such as:

$$\frac{m_W^2}{\Lambda_5^3} \bar{\chi} \chi W^{+\mu} W_{\mu}^{-} + \frac{m_Z^2}{2\Lambda_5^3} \bar{\chi} \chi Z^{\mu} Z_{\mu} , \quad (3.12)$$

where m_Z and m_W are the masses of the Z and W boson, W^{μ} and Z^{μ} are the fields of the gauge bosons, χ denotes the Dark Matter fields and Λ_5 is the effective field theory scale. Note that these operators are of true dimension 7, but reduce to effective dimension 5 once the Higgs vacuum expectation values, contained in the W and Z mass terms, are inserted. As such, one expects these that operators would naturally arise in UV complete models where Dark Matter interacts via a Higgs portal where heavy mediators couple to the Higgs or other fields in an extended Higgs sector. In such models the full theory may be expected to contain additional operators with Higgs-Dark Matter couplings [DFMQ13].

Concentrating on mono-gauge boson signals, the above operator induces signatures with \cancel{E}_T in conjunction with Z and W bosons at tree level, while at loop level it induces couplings to photon pairs and $Z\gamma$ through W loops. In these models, a clear relation exists between final states with photons, EW bosons and Higgs boson.

As shown in Fig. 3.21 kinematics of this model can be approximated by that of a simplified model including a high-mass scalar mediator exchanged in the s-channel described in Section 2.2.2. For this reason, the list of benchmark models with direct boson-DM couplings for photon, Z and W only includes dimension 7 operators: the scalar model with initial state radiation of an EW boson is already recommended and its results can be rescaled.

The Higgs+ \cancel{E}_T analysis, however, will not consider the scalar simplified model as benchmark, due to the very low sensitivity in early LHC analyses, and will instead use this dimension 5 operator.

To do The nomenclature in different models differs from literature: Λ_5 vs λ (??)

Figure 3.21: Comparison of the missing transverse momentum for the simplified model where a scalar mediator is exchanged in the s-channel and the model including a dimension-5 scalar contact operator, in the leptonic $Z+\cancel{E}_T$ final state

3.2.1.1 Parameter scan

The two parameters of this model are the scale of new physics λ and the DM particle mass. SM-DM coupling and new physics scale are related by $g_{\text{DM}} = (246 \text{ GeV})/\lambda$.

The initial value of the new physics scale λ chosen for the sample generation is 3 TeV; this is a convention and does not affect the signal kinematics; the cross-section of the samples can be rescaled according to the λ^3 dependence when deriving the constraints on this scale. However, more care should be given when rescaling Higgs+ E_T operators of higher dimensions, as different diagrams have a different λ dependence.

The DM mass values for the benchmark points to be simulated are chosen to span a sufficient Dark Matter range leading to different kinematics, that is within the LHC sensitivity for early searches and that is consistent across the various signatures and EFT operators. We therefore start the mass scan at $m_{\text{DM}} = 1 \text{ GeV}$, where collider experiments are complementary to direct and indirect detection and choose the last point corresponding to a DM mass of 1 TeV. We recommend a scan in seven mass points, namely:

$$m_{\text{DM}} = 1, 10, 50, 100, 200, 400, 800, 1300 \text{ GeV}.$$

A set of kinematic distributions from the Higgs+ E_T signature where the Higgs decays into two b -quarks is shown in Fig. 3.22, for points similar to those of the grid scan proposed.

3.2.2 Dimension 7 operators

The dimension-7 benchmark models contain the $SU(2)_L \times U(1)_Y$ gauge-invariant couplings between DM fields and the kinetic terms of the EW bosons. The CP-conserving scalar couplings of this type can be written as

$$\frac{c_1}{\Lambda_S^3} \bar{\chi} \chi B_{\mu\nu} B^{\mu\nu} + \frac{c_2}{\Lambda_S^3} \bar{\chi} \chi W_{\mu\nu}^i W^{i,\mu\nu}. \quad (3.13)$$

Here $B_{\mu\nu} = \partial_\mu B_\nu - \partial_\nu B_\mu$ and $W_{\mu\nu}^i = \partial_\mu W_\nu^i - \partial_\nu W_\mu^i + g_2 \epsilon^{ijk} W_\mu^j W_\nu^k$ are the $U(1)_Y$ and $SU(2)_L$ field strength tensor, respectively, and g_2 denotes the weak coupling constant. In the case of the pseudoscalar couplings, one has instead

$$\frac{c_1}{\Lambda_P^3} \bar{\chi} \gamma_5 \chi B_{\mu\nu} \tilde{B}^{\mu\nu} + \frac{c_2}{\Lambda_P^3} \bar{\chi} \gamma_5 \chi W_{\mu\nu}^i \tilde{W}^{i,\mu\nu}, \quad (3.14)$$

where $\tilde{B}_{\mu\nu} = 1/2 \epsilon_{\mu\nu\lambda\rho} B^{\lambda\rho}$ and $\tilde{W}_{\mu\nu}^i = 1/2 \epsilon_{\mu\nu\lambda\rho} W^{i,\lambda\rho}$ are the dual field strength tensors. In addition to the CP-conserving interactions (3.13) and (3.14), there are also four CP-violating couplings that are obtained from the above operators by the replacement $\bar{\chi} \chi \leftrightarrow \bar{\chi} \gamma_5 \chi$.

The effective interactions introduced in (3.13) and (3.14) appear in models of Rayleigh DM [WY12]. Ultraviolet completions where the operators are generated through loops of states charged under $U(1)_Y$ and/or $SU(2)_L$ have been proposed in [WY13] and

To do Clarify the reason why this happens in MadGraph5_aMC@NLO through explicit Lagrangian terms? (??)

(a) Leading b -jet transverse momentum(b) Leading b -jet pseudorapidity(c) Angular distance between the two leading b -jets

Figure 3.22: Comparison of the kinematic distributions for the two leading b -jets (from the Higgs decay) in the model with direct interactions between the Higgs boson and the DM particle, when varying the DM mass.

their LHC signatures have been studied in [LSWY13]. If these new charged particles are light, the high- p_T gauge bosons that participate in the \cancel{E}_T processes considered here are able to resolve the substructure of the loops. This generically suppresses the cross sections compared to the EFT predictions [HKU13], and thus will weaken the bounds on the interaction strengths of DM and the EW gauge bosons to some extent. Furthermore, the light charged mediators may be produced on-shell in pp collisions, rendering direct LHC searches potentially more restrictive than \cancel{E}_T searches. Making the above statements precise would require further studies beyond the timescale of this forum.

Since for $\Lambda_S = \Lambda_P$ the effective interactions (3.13) and (3.14) predict essentially the same value of the mono-photon, mono-Z and mono- W cross section [CNS⁺13, CHH15], we consider below only the former couplings. We emphasize however that measurements of the jet-jet azimuthal angle difference in $\cancel{E}_T + 2j$ events may be used to disentangle whether DM couples more strongly to the combination $B_{\mu\nu} B^{\mu\nu} (W_{\mu\nu}^i W^{i,\mu\nu})$ or the product $B_{\mu\nu} \tilde{B}^{\mu\nu} (W_{\mu\nu}^i \tilde{W}^{i,\mu\nu})$ of field strength tensors [CHLR13, CHH15].

After EW symmetry breaking the interactions (3.13) induce direct couplings between pairs of DM particles and gauge bosons. The corresponding Feynman rule reads:

$$\frac{4i}{\Lambda_S^3} g_{V_1 V_2} (p_1^{\mu_2} p_2^{\mu_1} - g^{\mu_1 \mu_2} p_1 \cdot p_2), \quad (3.15)$$

where p_i (μ_i) denotes the momentum (Lorentz index) of the vector field V_i and for simplicity the spinors associated with the DM fields have been dropped. The couplings $g_{V_i V_j}$ take the form:

$$\begin{aligned} g_{\gamma\gamma} &= c_w^2 c_1 + s_w^2 c_2, \\ g_{\gamma Z} &= -s_w c_w (c_1 - c_2), \\ g_{ZZ} &= s_w^2 c_1 + c_w^2 c_2, \\ g_{WW} &= c_2, \end{aligned} \quad (3.16)$$

with s_w (c_w) the sine (cosine) of the weak mixing angle. Note that our coefficients c_1 and c_2 are identical to the coefficients C_B and C_W used in [CHH15], while they are related via $k_1 = c_w^2 c_1$ and $k_2 = s_w^2 c_2$ to the coefficients k_1 and k_2 introduced in [CNS⁺13].

The coefficients c_1 and c_2 appearing in (3.16) determine the relative importance of each of the \cancel{E}_T channels and their correlations. For example, one observes that:

- Only c_2 enters the coupling between DM and W bosons, meaning that only models with $c_2 \neq 0$ predict a mono- W signal;
- If $c_1 = c_2$ the mono-photon (mono-Z) signal does not receive contributions from diagrams involving Z (photon) exchange;
- Since numerically $c_w^2/s_w^2 \simeq 3.3$ the mono-photon channel is particularly sensitive to c_1 .

3.2.2.1 Parameter scan

As stated above and shown in Ref. [NCC⁺14], the kinematic distributions for dimension-7 scalar and pseudoscalar operators only shows small differences. This has been verified from a generator-level study: the signal acceptance after a simplified analysis selection ($\cancel{E}_T > 350$ GeV, leading jet $p_T > 40$ GeV, minimum azimuthal difference between either of the two jets and the \cancel{E}_T direction > 0.4) is roughly 70% for both models, independent from the coefficients c_1 and c_2 . We therefore only suggest to generate one of the two models.

The differences in kinematics for the various signatures are negligible when changing the coefficients c_1 and c_2 , since these coefficient factorize in the matrix element. Only the case $c_1 = c_2 = 1$ is generated as benchmark; other cases are left for reinterpretation as they will only need a rescaling of the cross-sections.

Figure 3.23: \cancel{E}_T distribution for the dimension-7 model with a hadronically decaying Z in the final state, for the scalar and pseudoscalar operators representing direct interactions between DM and bosons. The values of the coefficients in the legend are multiplied by 100.

3.2.3 Higher dimensional operators

Many higher dimensional operators can induce signals of photons or $W/Z/H$ bosons in the final state. A complete list can be found in Refs. [CDM⁺14, BLW14b, PS14] and references therein.

Although with lower priority with respect to the operators above, a representative dimension-8 operators can be chosen as benchmark, with the form:

$$\frac{1}{\Lambda^4} \bar{\chi} \gamma^\mu \chi B_{\mu\nu} H^\dagger D^\nu H$$

In this case, the new physics scale is Λ is connected with the coupling of the DM as $y_\chi = \frac{1}{\Lambda^4}$. An advantage of this operator is that it includes all signatures with EW bosons, allowing to assess the relative sensitivity of the various channels with the same model. The kinematics for this operator is different with respect to other

To do Is more detail needed here? (??)

operators, leading to a harder \cancel{E}_T spectrum, as illustrated by comparing the leading b -jet distribution for the dimension 5 operator to the dimension 8 operator.

(a) Dimension 5 operator

(b) Dimension 7 operator

Figure 3.24: Comparison of the transverse momentum for the leading b -jet from the Higgs decay for a dimension 5 and dimension 7 operator with direct boson-DM couplings.

3.2.4 Validity of EW contact operators and possible completions

It is important to remember that the operators described in this section may present problems in terms of the validity of the contact interaction approach for the energy scales reached at the LHC.

As outlined in [BLW14b], designing very high \cancel{E}_T search signal regions that are exclusively motivated by the hard \cancel{E}_T spectra of the dimension 7 and 8 operators will mean that the momentum transfer in the selected events is larger. This in turn means that processes at that energy scale (mediators, particles exchanged in loops) are accessible, and a simple contact interaction will not be able to correctly describe the kinematics of these signals.

Contact interaction operators like the ones in this section remain useful tools for comparison of the sensitivity of different search channels, and for reinterpretation of other models under the correct assumptions. To date, there are no UV-complete models available for most of those operators: dimension-7 operators are particularly challenging since their completion involves loops ³.

However, this may be the focus of future theoretical exploration, as discussed in Ref. [CHH15]. An example of a complete model for scalar DM corresponding to the dimension-5 operator is provided in the Appendix A. Providing results for the pure EFT limit of these models will prove useful to cross-check the implementation of future.

Given these considerations, the recommendations on the presentation of the results for these models are:

- Deliver fiducial limits on the cross section of any new physics events, without any model assumption, according to the guidelines in Appendix B.
- Assess the percentage of events that pass a condition of validity for the EFT approximation that only depends, and present results removing of the invalid events using the procedure in Section 5 alongside the raw EFT results;

THE IMPLEMENTATION FOR THESE MODELS IS DISCUSSED IN APPENDIX 4.2.2.

³ An example case for the need of loop completions is a simplified model with an additional scalar exchanged at tree level. The scalar couples to WW and ZZ in a gauge-invariant way, Integrating out the mediator does not lead to the Lorentz structure of a dimension-7 operator, so it is not possible to generate dimension-7 operators that satisfy gauge and Lorentz invariance at the same time. A model with a spin-1 mediator cannot be considered as an candidate for completion either, since dimension-7 operators only have scalar or pseudoscalar couplings.

4

Implementation of Models

4.1 Implementation of s -channel and other models for $\cancel{E}_T + X$ analyses

In the studies to date, a fair number of different Monte Carlo tools have been used to simulate signals. In this Chapter, we make recommendations and provide settings to promote uniformity in the simulations produced by the collaborations. These recommendations are based on the current status of the available codes. We also aim for simplicity, so that fewer tools need be used if the theoretical quality does not suffer.

4.1.1 Implementation of “ s -channel” models for mono-jet signature

These models include those referred to as DMV, DMA, DMS and DMP and discussed in Secs. 2.1 and 2.2. The necessary simulations are geared for monojet analyses, i.e. those with a few jets and \cancel{E}_T . In particular, the \cancel{E}_T spectrum depends upon the accurate simulation of parton radiation from the initial state. For the DMV and DMA models, we recommend POWHEG [HKR13], since it includes NLO corrections for these models. The NLO corrections result in a substantial reduction in the dependence on the choice of the renormalization and factorization scale and hence the theoretical uncertainty on the signal prediction. For the central choice of renormalization and factorization scales, the NLO corrections also provide a minor enhancement in the cross section.¹

For the DMS and DMP models, the lowest order process already involves a one-loop amplitude in QCD. Because of this complexity, NLO calculations for these signals do not yet exist with a parton shower interface. For these spin-0 mediators in the mono-jet final state, the top-quark loop is the most important consideration. The matrix element implementation of the s -channel spin-0 mediated DM production is available in MCFM [FW13, HKS15] and POWHEG [HR15] with the full top-loop calculation at LO. The POWHEG and MCFM implementations include the finite top quark mass dependence for DM pair production with 1 parton at LO. For consistency with the spin-1 generation, we recommend using POWHEG.

Here, we document some specific settings needed to run the

¹ spin-0 and spin-1 mediator models will also be provided in the near future to the same precision in MADGRAPH5_AMC@NLO [A⁺14b].

POWHEG generation for the Dark Matter models. POWHEG parameter cards for all models can be found on the Forum SVN repository [For15i, For15j, For15k, For15j].

4.1.1.1 POWHEG configuration for DM models

The latest POWHEG release is available for download using the instructions at <http://powhegbox.mib.infn.it/>. The forum recommends using at least version x.xxx.

- POWHEG can generate either unweighted (uniformly-weighted) or weighted events. The relevant keywords in the input card are `bornsuppfact` and `bornktmin`.

1. unweighted events:

`bornsuppfact`: negative or absent
`bornktmin` <PT>

This runs the program in the most straightforward way, but it is likely not the more convenient choice, as will be explained below. POWHEG will generate unweighted events using a sharp lower cut (with value PT) on the leading-jet p_T . Since this is a generation cut, the user must check that the choice of `bornktmin` does not change the cross section for signal events passing analysis selections. It is good practice to use as a value in the input card a transverse momentum 10-20% smaller than the final analysis selection on \cancel{E}_T , and check that the final result is independent, by exploring an even smaller value of `bornktmin`. The drawback of using this mode is that it is difficult to populate well, and in a single run, both the low- p_T region as well as the high- p_T tail.

2. weighted events:

`bornsuppfact` <PTS>
`bornktmin` <PT>

POWHEG will now produce weighted events, thereby allowing to generate a single sample that provides sufficient statistics in all signal regions. Events are still generated with a sharp lower cut set by `bornktmin`, but the `bornsuppfact` parameter is used to set the event suppression factor according to

$$F(k_T) = \frac{k_T^2}{k_T^2 + \text{bornsuppfact}^2} . \quad (4.1)$$

In this way, the events at, for instance, low \cancel{E}_T , are suppressed but receive higher weight, which ensures at the same time higher statistics at high \cancel{E}_T . We recommend to set `bornsuppfact` to 1000.

The `bornktmin` parameter can be used in conjunction with `bornsuppfact` to suppress the low \cancel{E}_T region even further. It is recommended to set `bornktmin` to one-half the value of the lowest \cancel{E}_T selection. For instance, for the event selection used

in the CMS/ATLAS monojet analyses, assuming the lowest \cancel{E}_T region being defined above 300 GeV, the proposed value for `bornktmin` is 150. However, this parameter should be set keeping in mind the event selection of all the analyses that will use these signal samples, and hence a threshold lower than 150 may be required.

- Remove the `runningwidth` keyword, or set it to 0, which is the default value. Running with fixed widths is the recommended option. Although there are limitations, this is the more straightforward, simple and transparent option, and it was used for these Forum studies.

The alternative, a running width for the propagator of the s -channel mediator, can be selected by setting `runningwidth` to 1. In this case the denominator of the mediator's propagator is modified:

$$Q^2 - M^2 + i M \Gamma \rightarrow Q^2 - M^2 + i Q^2 \frac{\Gamma}{M},$$

where Q is the virtuality of the mediator, and M and Γ are its mass and width respectively. See Ref. [BBB⁺89] for a discussion.

- Set the parameters defining the bounds on the invariant mass of the Dark Matter pair, `mass_low` and `mass_high`, to -1. In this way, POWHEG will assign values internally.
- The minimal values for `ncall1`, `itmx1`, `ncall2`, `itmx2` are 250000, 5, 1000000, 5 for the vector model, respectively.
- The minimal values for `ncall1`, `itmx1`, `ncall2`, `itmx2` are 100000, 5, 100000, 5 for the scalar top-loop model, respectively.
- When NLO corrections are included (as for instance in the vector model), negative-weighted events could happen and should be kept in the event sample, hence `withnegweights` should be set to 1. If needed, their fraction can be decreased by setting `foldsci` and `foldy` to bigger value (2 for instance). `foldphi` can be kept to 1.
- Since the scalar model with top-loop is computed as a leading order process, set `L0events` and `bornonly` are set to 1 internally.
- One should use the automatic calculation of systematic uncertainties associated with the choice of hard scale and PDFs as described in Section 6.
- `idDM` is the integer that identifies the DM particle in the Monte Carlo event record. This should be chosen so that other tools can process the POWHEG output properly.

POWHEG in itself is not an event generator and must be interfaced with a tool that provides parton showering, hadronization, *etc.* For some time, a PYTHIA 8 [SAC⁺15] interface has existed for POWHEG. The PYTHIA 8 runtime configuration is the following:

```

1729 POWHEG:veto = 1
1730 POWHEG:pTdef = 1
1731 POWHEG:emitted = 0
1732 POWHEG:pTemt = 0
1733 POWHEG:pThard = 0
1734 POWHEG:vetoCount = 100
1735 SpaceShower:pTmaxMatch = 2
1736 TimeShower:pTmaxMatch = 2

```

As always, it is recommended to use the latest PYTHIA 8 release, available at <http://home.thep.lu.se/~torbjorn/Pythia.html>. At the time of this report, the latest version is 8.209.

4.1.2 Implementation of models with matching

For the models discussed in the previous section, it is important to calculate the hard process as accurately as possible in QCD. For many other signal models, the E_T signature depends more upon the production and decay of the mediator. Also, for some models, no NLO+parton shower implementations currently exist. In these cases, one usually resorts to a LO+parton shower implementation, sometimes supplemented by several LO processes matched with the parton shower.

Here, we consider the example of an EFT model produced in association with up to 2 additional QCD partons. A Monte Carlo sample based on this model could be used to cross-check a similar POWHEG sample, for example. The methodology described here could also be used for the t -channel model discussed in Sec. 2.3,

For the calculation of tree-level, signal models, we recommend MADGRAPH5_AMC@NLO. MADGRAPH5_AMC@NLO provides a flexible and easy-to-use framework for implementing new models via the FEYNRULES package. MADGRAPH5_AMC@NLO can produce both LO and NLO calculations, though not all signal models can be generated currently at NLO.² The parton matching is performed in order to avoid double counting of the partons from matrix elements and parton showering. Several parton matching techniques are available. Based on some comparative studies [A⁺08], there is some advantage to using the CKKW-L matching scheme [LP12] implemented in PYTHIA 8. Alternatively, one can use the k_T -MLM scheme also implemented in PYTHIA 8.

² For truly NLO, matched samples, a different matching scheme would be used.

4.1.2.1 Generation of the LHE file

The example presented here is a D5 EFT model, and includes tree-level diagrams with $\chi\bar{\chi}+0,1,2$ partons. The model is encapsulated as a UFO file in the SVN repository (ref here). MADGRAPH5_AMC@NLO, like POWHEG, is not in itself an event generator, but must be interfaced with an event generator through an LHE file. The production of the LHE file proceeds through setting the process parameters and the run parameters.

The process parameters are:

```

1775 import model MODELNAME
1776 generate p p > chi chi~ [QCD] @0
1777 add process p p > chi chi~ j [QCD] @1
1778 add process p p > chi chi~ j j [QCD] @2

```

The runtime parameters are more numerous, and define the collider properties, PDF sets, etc. The specific parameters needed for matching are, for example:

```

1782 ickkw = 0
1783 ktdurham = matching scale
1784 dparameter = 0.4
1785 dokt = T
1786 ptj=20
1787 drjj=0
1788 mmjj=0
1789 ptj1min=0

```

For different kinds of matching, a different choice of ickkw and related parameters would be made.

4.1.2.2 Implementation of the CKKW-L matching

To illustrate the settings related to parton matching, the EFT D5 samples were generated with MADGRAPH5_AMC@NLO version 2.2.2 and showered in PYTHIA 8.201.

The PYTHIA 8 parameters for the CKKW-L k_T -merging scheme are:

```

1798 Merging:ktType          = 1
1799 Merging:TMS             = matching scale
1800 1000022:all = chi chi~ 2 0 0 30.0 0.0 0.0 0.0 0.0
1801 1000022:isVisible = false
1802 Merging:doKTMerging     = on
1803 Merging:Process          = pp>{chi,1000022}{chi~ -1000022}
1804 Merging:nJetMax         = 2

```

The matching scales should be the same for the generation and parton showering. In the model implementation, the particle data group ID 1000022 is used for weakly interacting dark matter candidates. Since this is a Majorana particle by default (with no corresponding anti-particle), and the model produces a DM Dirac fermion, the particle properties are changed accordingly. Also, the DM mass is set to 30 GeV. The Merging:Process command specifies the lowest parton emission process generated in MADGRAPH5_AMC@NLO and Merging:nJetMax = 2 gives the maximum number of additional parton emissions with respect to the lowest parton emission process.

In general, it is desired to take the hard parton emissions from the matrix element generation in MADGRAPH5_AMC@NLO and allow PYTHIA 8 to take care of soft emissions only. The transition between these two regimes is defined by the matching scale and its

optimal value can be determined by studying the cross-section as a function of the number of jets (differential jet rates). The differential rates $\frac{dN_{i \rightarrow j}}{d \log_{10}(k_{\text{cut}})}$ give the number of events which pass from i jets to j jets as the k_T value increases beyond k_{cut} . An optimal matching scale should lead to smooth differential jet rates.

Two examples of differential jet rates, using matching scale 30 GeV and 80 GeV, from the EFT D5 sample generated as described in the previous section are given in Fig. 4.1 and 4.2, respectively. Although a kink is visible around the matching scale value in both cases, the 80 GeV scale leads to smoother distributions. In order to find the optimal matching scale, additional samples with matching scale 50, 70, and 90 GeV are generated as well and a detailed comparison of the differential jet rates close to the transition region is shown in Fig. 4.3. The largest differences among the samples are visible for the $1 \rightarrow 2$ jets transition where the 30 GeV and 50 GeV scale lead to a drop of the rates around the matching scale values. On the contrary, there is a hint of an increased rate around the matching scale value in the sample generated with the 90 GeV scale. Therefore, we recommend to use 80 GeV as the base-line matching scale.

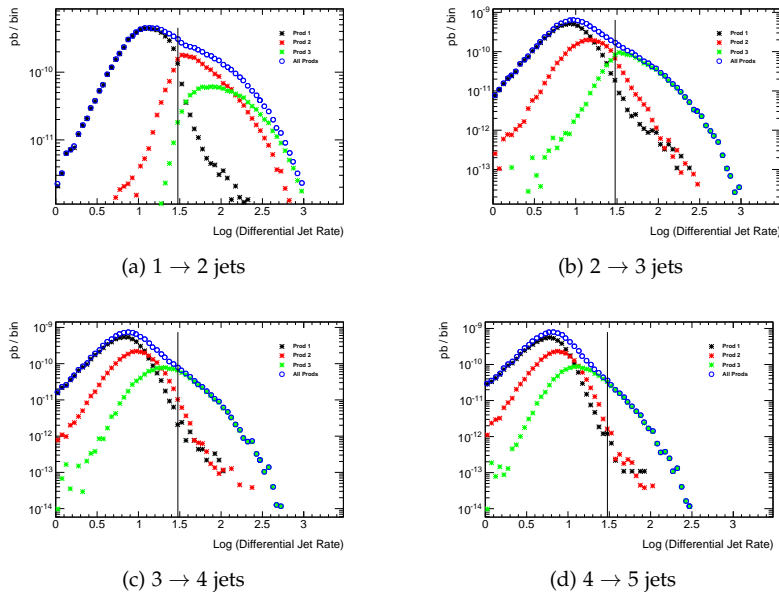

Figure 4.1: Distributions of differential jet rates $\frac{dN_{i \rightarrow j}}{d \log_{10}(k_{\text{cut}})}$ for EFT D5 sample with CKKW-L matching scale at 30 GeV. The 0-, 1- and 2-parton emission samples are generated separately and indicated in the plots as Prod 1, Prod 2 and Prod 3, respectively. A vertical line is drawn at the matching scale.

The prescription for the event generation given in Section 4.1.2.2 starts with the emission of 0 partons and ends with maxim 2 partons in addition. Producing the samples separately allows to investigate the relative composition of the individual samples in various parts of the phase space. Figure 4.4 shows the \cancel{E}_T distribution of the EFT D5 sample with the matching scale at 80 GeV. The plot reveals that the 0-parton sample gives the dominant contribution in the region below the matching scale value that rapidly decreases at higher \cancel{E}_T . Assuming the lowest analysis \cancel{E}_T cut in Run-2 mono-jet analyses at 300 GeV, the generation of the 0-parton emission sample can be safely omitted as it only gives $< 1\%$ contribution at

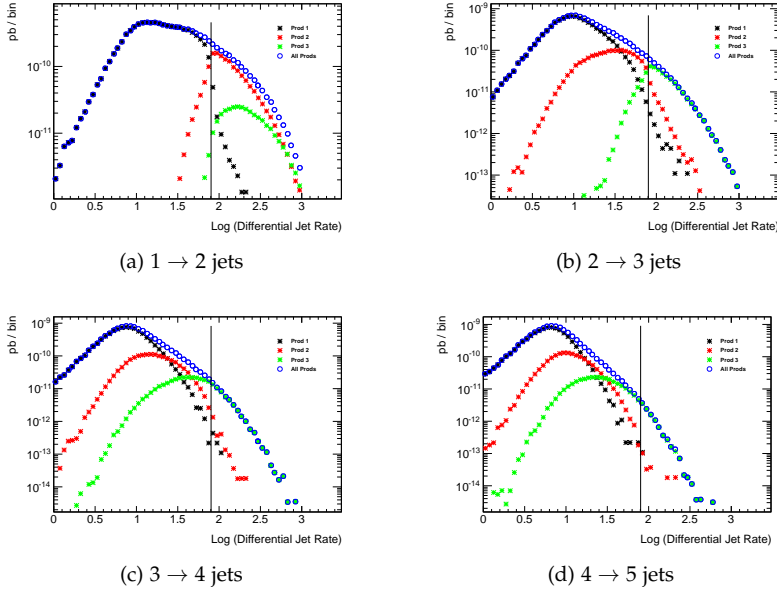

Figure 4.2: Distributions of differential jet rates $\frac{dN_{i \rightarrow j}}{d \log_{10}(k_{\text{cut}})}$ for EFT D5 sample with CKKW-L matching scale at 80 GeV. The 0-, 1- and 2-parton emission samples are generated separately and indicated in the plots as Prod 1, Prod 2 and Prod 3, respectively. A vertical line is drawn at the matching scale.

$\cancel{E}_T > 300$ GeV. For the 1- and 2-parton emission samples, one can use a generator cut on the leading parton p_T , ptj1min , in order to avoid generating low \cancel{E}_T events that are irrelevant for the analysis.

In order to describe the signal kinematics correctly and save time during MC production, the parton emissions will only be generated up to a certain multiplicity. The higher multiplicity samples usually have small enough cross sections and the corresponding parts of the phase space can be sufficiently approximated by parton showering in PYTHIA 8. A dedicated study comparing samples generated with up to 1-, 2-, or 3-parton multiplicities was performed, using again the settings for the CKKW-L k_T -merging with the 80 GeV matching scale and the `Merging:nJetMax` parameter adjusted accordingly. Figure 4.5 shows the \cancel{E}_T distribution of the samples at $\cancel{E}_T > 250$ GeV.

With an event selection requiring \cancel{E}_T and the leading jet p_T being larger than 250 GeV, the sample generated with up to 1 parton has 10.3% larger yield compared to the sample with up to 3 partons, while the yield of the sample with up to 2 partons is only 2.3% larger. If an additional cut is applied allowing for up to 3 jets with $p_T > 30$ GeV, the agreement improves to 3.2% larger for up to 1 parton and 0.7% larger for up to 2 partons, compared with up to 3 partons. A similar comparison is shown in Fig. 4.6 for the jet multiplicity in the events with the leading jet $p_T > 250$ GeV, where an agreement at the level of $\sim 3\%$ between the samples with up to 2 and 3 parton emissions is observed for number of jets up to 7. This justifies it is sufficient to produce samples with up to 2 parton emissions only at the generator level and ignore generating higher parton emissions.

(a) $1 \rightarrow 2$ jets(b) $2 \rightarrow 3$ jets(c) $3 \rightarrow 4$ jets(d) $4 \rightarrow 5$ jets

Figure 4.3: Distributions of differential jet rates $\frac{dN_{i \rightarrow j}}{d \log_{10}(k_{\text{cut}})}$ for EFT D5 sample with CKKW-L matching scale at 30, 50, 70, 80 and 90 GeV. A zoom of the region around the matching scale values is shown on right.

Figure 4.4: Missing transverse momentum distributions for EFT D5 sample with CKKW-L matching scale at 80 GeV. Individual contributions from the 0-, 1- and 2-parton emission samples are shown.

(a) No jet multiplicity cut

(b) $N_{\text{jet}} \leq 3$ 

Figure 4.6: Multiplicity of jets with $p_T > 30$ GeV and $|\eta| < 2.8$ for EFT D5 sample with CKKW-L matching scale at 80 GeV produced with maximum 1 (black), 2 (red) and 3 (blue) partons emitted at the generator level. The ratios are shown with respect to the latter sample. The leading jet p_T is required to be larger than 250 GeV.

4.1.3 Implementation of models for EW final states

These models are generated at leading order with MADGRAPH5_AMC@NLO 2.2.2, using PYTHIA 8 for the parton shower. Parameter cards can be found on the Forum SVN repository [For15a]. No parton matching is currently implemented, since the visible signal comes from the production of a heavy SM boson. As a result, no special runtime configuration is needed for PYTHIA 8.

4.1.4 Implementation of models with heavy flavor quark signatures

The models for the $t\bar{t}$ and $b\bar{b}$ signatures are generated at leading order with MADGRAPH5_AMC@NLO 2.2.2, using PYTHIA 8 for the parton shower. No matching is currently implemented. Parameter cards can be found on the Forum SVN repository [For15d].

We simulate the bFDM model at LO+PS using MADGRAPH5_AMC@NLO v2.2.3 and PYTHIA 8 for the parton shower. Parton matching is needed in the case of the $b\bar{b}+\cancel{E}_T$ final state, but it has not been studied within the Forum. The corresponding card files can be found on the Forum SVN repository [For15f].

4.1.4.1 Quark flavor scheme and masses

In this particular model we recommend an additional care when choosing the flavor scheme generation and whether quarks should be treated as massive or massless.

The production of DM+ $b\bar{b}$, Dark Matter in association with b jets via a decay of a (pseudo) scalar boson, is dominated in simplified mediator models by the gluon-gluon initiated production, similar to the production of $Z+b\bar{b}$ at the LHC. The $Z+b\bar{b}$ process has been studied in detail in the $Z(\ell\ell)+b$ -jets final state, which can be used to validate both the modeling of DM+ $b\bar{b}$ and, its main background, $Z(\nu\nu)+b\bar{b}$. In this context, the p_T of the Z boson is related to the observed MET, whereas the b -jet kinematics determines the ratio of mono- b /di- b signatures in the detector.

For basic kinematic criteria applied to $Z+b\bar{b}$ production, this process leads in $\sim 90\%$ of the events to a signature with only 1 b -jet in the acceptance (' $Z+1b$ -jet production') and only in $\sim 10\%$ of the events to a signature with 2 b -jets in the detector (' $Z+2b$ -jets production'). The production cross section of the $Z+b\bar{b}$ process are calculated in the 'five-flavor scheme', where b quarks are assumed massless, and the 'four-flavor scheme', where massive b quarks are used [CEMW04, MMW05, CEMW06], and data favor the cross-section predictions in the five-flavor scheme [C⁺14]. We therefore recommend to calculate the cross sections of these models in the 5-flavor scheme, as in the repository. The PDF used to calculate these cross section is NNPDF3.0 (lhaid 263000).

It is found that the best modeling of two b -quarks final states is achieved using a 4-flavor scheme and a massive treatment of the b -quarks [C⁺14, C⁺13, Col15]. We recommend to use in the

generation NNPDF3.0 set (lhaid 263400). Since figure 4.7 shows that there is no significant difference in the kinematics between either flavor scheme used for $DM+b\bar{b}$ production, we recommend the 4-flavor scheme to follow the observation in the $Z+b\bar{b}$ measurements.

Figure 4.7: Comparison of the jet multiplicity (left) and angular correction $\Delta R(j_1, j_2)$ (right) for the $DM+b\bar{b}$ scalar model generated in the 4-flavor and 5-scheme. The samples are generated for $m_\chi = 1$ GeV and $m_\phi = 10$ GeV.

4.2 Implementation of specific models for $V + \cancel{E}_T$ analyses

4.2.1 Model implementation for mono-Higgs models

All three Higgs+ \cancel{E}_T models are generated at leading order with MADGRAPH5_AMC@NLO 2.2.2, using PYTHIA 8 for the parton shower. No matching is needed. The MADGRAPH5_AMC@NLO implementations of the scalar and vector models can be found on the Forum SVN repository [For15g], while the 2HDM model can be found at this link [For15b].

In all cases, it is recommended not to handle the h decay through MADGRAPH5_AMC@NLO as it does not include the proper h branching ratios, or, if using MADGRAPH5_AMC@NLO, then the resulting cross section should be rescaled to match onto the correct branching ratio.

4.2.1.1 MADGRAPH5_AMC@NLO details for scalar mediator Higgs+MET model

In this model, the contribution from the $gghS$ box is included through an effective Lagrangian evaluated in the large m_t limit. This may overestimate the rates of the $h + \cancel{E}_T$ signal [HKU13], but a full evaluation is left to future studies.

4.2.1.2 MADGRAPH5_AMC@NLO details for 2HDM Higgs+MET model

The two couplings that can be changed in the implemented model follow the nomenclature below:

- $Tb - \tan \beta$
- $gz - g_z$, gauge coupling of Z' to quarks

The other couplings are not changed, including gx (the $A\bar{\chi}\chi$ coupling) which has little impact on the signal. $\sin \alpha$ is fixed internally such that $\cos(\beta - \alpha) = 0$. The width of the Z' and A can be computed automatically within MADGRAPH5_AMC@NLO. The couplings here don't affect the signal kinematics, so they can be fixed

to default values and then the signal rates can be scaled appropriately.

The nomenclature for the masses in the implemented model is:

- MZp - PDG ID 32 - Z'
- MA0 - PDG ID 28 - A
- MX - PDG ID 1000022 - dark matter particle

The other masses are unchanged and do not affect the result.

Both $Z' \rightarrow hZ(\bar{\nu}\nu)$ and $Z' \rightarrow hA(\bar{\chi}\chi)$ contribute to the final state, scaling different with model parameters. We recommend to generate them separately, and then add the two signal processes together weighted by cross sections.

4.2.2 Implementation of EFT models

These models are generated at leading order with MADGRAPH5_AMC@NLO 2.2.2, using PYTHIA 8 for the parton shower. No matching is currently implemented. Parameter cards can be found on the Forum SVN repository: [For15g] for operators with Higgs+MET final states and [For15c] for $W/Z/\gamma$ final states.

Presentation of EFT results

Most of this report has focused on simplified models. In this Chapter, we wish to emphasize the applicability of Effective Field Theories (EFTs) in the interpretation of DM searches at the LHC. Given our current lack of knowledge about the nature of a DM particle and its interactions, it appears mandatory to provide the necessary information for a model independent interpretation of the collider bounds. This approach should be complemented with an interpretation within a choice of simplified models. We note that, even though EFT benchmarks are only valid in given conditions, the results provided by the current list of simplified models cannot always characterize the breadth of SM-DM interactions. In at least one case, composite WIMPs [Nus85, Kap92, BFT10], the contact interaction framework is the correct one to constrain new confinement scales.

Ideally, experimental constraints should be shown as bounds of allowed signal events in the kinematic regions considered for the search, as detailed in Appendix B. A problematic situation is the attempt to derive a limit on nucleon-dark matter scattering cross sections from EFT results based on collider data ¹. Experiments that directly probe the nucleon-dark matter scattering cross section are testing the regime of small momentum transfers, where the EFT approximation always holds. Collider experiments, though, are sensitive to large momentum transfers: this is a regime where careful treatment is necessary since the condition of applicability of the EFT may not hold.² Therefore, especially in the case when constraints from different experiments are compared, we suggest to assess the applicability of EFT benchmark models, rather than abandon them. Therefore, whenever EFT models are used, collider experiments should always assess their applicability using one of the several prescriptions in the literature [BDSMR14, BDSG⁺14, BDSJ⁺14, ATL15d, RWZ15], especially when constraints from other experiments are compared.

We first illustrate the complications that can arise with EFTs at colliders by considering an effective interaction

$$\mathcal{L}_{\text{int}} = \frac{(\bar{q}\gamma_{\mu}q)(\bar{\chi}\gamma^{\mu}\chi)}{M_*^2} = (\bar{q}\gamma_{\mu}q)(\bar{\chi}\gamma^{\mu}\chi)\frac{g}{\Lambda^2}$$

that couples quarks and DM χ fields.³ The strength of this inter-

¹ Comparisons between constraints from different experiments meant to highlight their complementarity should be expressed as a function of the model parameters rather than on derived observables; however this is a point that should be developed further after the conclusion of the work of this Forum.

² Furthermore, mapping EFT results from high to low momentum requires particular care for some of the operators, see Ref. [DP15] for a thorough discussion.

³ The *exact* operator chosen is not important.

action is parametrized by $\frac{1}{M_*^2} = \frac{g}{\Lambda^2}$. A monojet signature can be generated from this operator by applying perturbation theory in the QCD coupling. An experimental search will place a limit on M_* . For a fixed M_* , a small value of g will correspond to a small value of Λ . The EFT approximation breaks down if $Q > \Lambda$, where Q is a typical hard scale of the process. The limit on small g can only be reliable if the kinematic region $Q > \Lambda$ is removed from the event generation. However, if a fraction of events is removed from the prediction, the corresponding value of g must increase to match the experimental limit on M_* . On the other hand, if, for the same value of M_* , a large Λ is assumed so that the full set of events fulfill the EFT validity condition, a large value of g is required, raising the question if perturbation theory is even applicable.

In the first part of this Chapter, we summarize two methods that have been advocated to truncate events that do not fulfill the condition necessary for the use of an EFT. These methods are described in detail in Refs. [BDSMR14, BDSG⁺14, BDSJ⁺14, ATL15d, RWZ15, BLW14b]. We then propose a recommendation for the presentation of EFT results for early Run-2 LHC searches.

5.1 Procedures for the truncation of EFT benchmark models

5.1.1 EFT truncation using the momentum transfer and information on UV completion

In the approach described in Ref. [BDSG⁺14], the EFT prediction is modified to incorporate the effect of a propagator for a relatively light mediator. For a tree-level interaction between DM and the SM via some mediator with mass M_{med} , the EFT approximation corresponds to expanding the propagator for the mediator in powers of $Q_{\text{tr}}^2/M_{\text{med}}^2$, truncating at lowest order, and combining the remaining parameters into a single parameter M_* (connected to the scale of the interaction Λ in the literature). For an example scenario with a Z' -type mediator (leading to some combination of operators D5 to D8 in the notation of [GIR⁺10] for the EFT limit), this corresponds to setting

$$\frac{g_{\text{DM}}g_{\text{q}}}{Q_{\text{tr}}^2 - M_{\text{med}}^2} = -\frac{g_{\text{DM}}g_{\text{q}}}{M_{\text{med}}^2} \left(1 + \frac{Q_{\text{tr}}^2}{M_{\text{med}}^2} + \mathcal{O}\left(\frac{Q_{\text{tr}}^4}{M_{\text{med}}^4}\right) \right) \simeq -\frac{1}{M_*^2}, \quad (5.1)$$

where Q_{tr} is the momentum carried by the mediator, and $g_{\text{DM}}, g_{\text{q}}$ are the DM-mediator and quark-mediator couplings respectively.⁴ A minimal condition that must be satisfied for this approximation to be valid is that $Q_{\text{tr}}^2 < M_{\text{med}}^2 = g_{\text{DM}}g_{\text{q}}M_*^2$. This requirement avoids the regions: $Q_{\text{tr}}^2 \sim M_{\text{med}}^2$, in which case the EFT misses a resonant enhancement, and it is conservative to ignore this enhancement; and $Q_{\text{tr}}^2 \gg M_{\text{med}}^2$, in which case the signal cross section should fall according to a power of Q_{tr}^{-1} instead of M_{med}^{-1} . The latter is the problematic kinematic region.

⁴ Here, we ignore potential complications from the mediator width when the couplings are large.

The condition $Q_{\text{tr}}^2 < M_{\text{med}}^2 = g_{\text{DM}q} M_*^2$ was applied to restrict the kinematics of the signal and remove events for which the high-mediator-mass approximation made in the EFT would not be reliable. This leads to a smaller effective cross-section, after imposing the event selection of the analysis. This truncated signal was then used to derive a new, more conservative limit on M_* as a function of $(m_{\text{DM}}, g_{\text{DM}q})$.

For the example D5-like operator, where the cross section σ scales as M_*^{-4} , there is a simple rule for converting a rescaled cross section into a rescaled constraint on M_* : if the original limit is based on a simple cut-and-count procedure. Defining $\sigma_{\text{EFT}}^{\text{cut}}$ as the cross section truncated such that all events pass the condition $\sqrt{g_{\text{DM}q}} M_*^{\text{rescaled}} > Q_{\text{tr}}$, we have

$$M_*^{\text{rescaled}} = \left(\frac{\sigma_{\text{EFT}}}{\sigma_{\text{EFT}}^{\text{cut}}(M_*^{\text{rescaled}})} \right)^{1/4} M_*^{\text{original}}, \quad (5.2)$$

which can be solved for M_*^{rescaled} via either iteration or a scan. Similar relations exist for a given UV completion of each operator. The details and application of this procedure to ATLAS results can be found in Ref. [ATL15d] for a range of operators. We reiterate: knowledge of the UV completion for a given EFT operator was necessary for this procedure; this introduces a model-dependence that was not present in the non-truncated EFT results.

Currently, simplified models (including the full effect of the mediator propagator) are available for comparison with the data, and since knowledge of the simplified models is needed for the truncation procedure, there is no reason to apply this prescription. Instead, the simplified model limit for large M_* can be presented for interpretation in terms of EFT operators.

5.1.2 EFT truncation using the center of mass energy

The procedure presented in the previous section was predicated on some knowledge of the simplified model. This led to the identification of the mass of the DM pair as the relevant kinematic quantity to use in a truncation procedure. In general, if no assumption is made about the underlying dynamics, it is more conservative to place a limit on the total center of mass energy E_{cm} of the DM production process. Furthermore, the direct connection between the mass scale of the EFT validity, M_{cut} , and the mass scale that normalizes the EFT operator, M_* , is unknown. For such cases, Refs.[RWZ15, BLW14b] proposed a procedure to extract model independent and consistent bounds within the EFT that can be applied to any effective Lagrangian describing the interactions between the DM and the SM. This procedure provides conservative limits that can be directly reinterpreted in any completion of the EFT. The condition ensuring that the EFT approximation is appropriate is:

$$E_{\text{cm}} < M_{\text{cut}}. \quad (5.3)$$

The relationship between M_{cut} and M_* can be parameterized by an *effective coupling strength* g_* , such that $M_{\text{cut}} = g_* M_*$. A scan over values of g_* provides an indication of the sensitivity of the prediction to the truncation procedure. In the Z' -type model considered above, g_* is equal to $\sqrt{g_{\text{DM}} g_q}$. The resulting plots are shown in [RWZ15] for a particular effective operator.

The advantage of this procedure is that the obtained bounds can be directly and easily recast in any completion of the EFT, by computing the parameters M_* , M_{cut} in the full model as functions of the parameters of the complete theory. On the other hand, the resulting limits will be weaker than those obtained using Q_{tr} and a specific UV completion.

5.1.3 Consideration for shape analyses

If a search is not simply a counting experiment and exploits the shapes of kinematic distributions, any of the two conditions on the momentum transfer should be applied on the benchmarks using generator level information, by discarding events that are invalid, and the limit derived from the truncated shape must be recalculated. This provides the necessary rescaling of the cross section while keeping the information on the change in the kinematic distributions due to the removal of the invalid events.

5.1.4 Sample results of EFT truncation procedures

An example of the application of the two procedures to the limit on M_* from Ref. [ATL14d] as a function of the product of the couplings is shown in Figure 5.3. Only the region between the dashed and the solid line is excluded. It can be seen that the procedure from [RWZ15] outlined in Section 5.1.2, shown in blue, is more conservative than the procedure from Refs. [BDSG⁺14, ATL15d], described in Section 5.1.1.

Figure 5.1: 95% CL lower limits on the scale of the interaction of the D5 operator at 14 TeV, after the two truncation procedures. The procedure from [RWZ15] outlined in Section 5.1.2 is shown in blue, while the procedure from Refs. [BDSG⁺14, ATL15d], described in Section 5.1.1 is shown in red. Only the region between the dashed and the solid lines is excluded.

To do This plot needs to be clarified further: what is the statistics for the truncation with sHat, and does this cause the sudden drop at $\sqrt{g}=2$ (??)

5.1.5 Comments on unitarity considerations

A further consideration applicable to EFT operators at hadron colliders is the potential violation of unitarity. An analysis of the operator $\frac{\bar{q}\gamma_\mu q \tilde{\chi}\gamma^\mu \chi}{M_*^2}$ provides the limit:

$$M_* > \sqrt{s} \sqrt{\frac{\sqrt{3}}{4\pi} \beta(s)}, \quad (5.4)$$

where \sqrt{s} is (maximally) the collider energy and $\beta(s)$ is the DM velocity [SV12]. Constraints for other operators have also been derived [EY14]. This constraint on M_* still is open to interpretation, since the relation to M_{cut} is not resolved, except for a specific simplified model. Derived limits on M_* should be compared to this unitarity bound to check for consistency.

To do Waiting for input from J. Alcaraz (??)

5.2 Recommendation for presentation of EFT results

In this report, we make two recommendations for the presentation of collider results in terms of Effective Field Theories for the upcoming Run-2 searches. A full discussion of the presentation of collider results in relation to other experiments is left to work beyond this Forum, where ATLAS, CMS, the theory community and the Direct and Indirect Detection communities are to be involved.

We divide the EFT operators in two categories: those that can be mapped to one or more UV-complete simplified models, such as those commonly used in LHC searches so far and detailed in [GIR⁺10], and those for which no UV completion is available, such as those outlined in Section 3.2.

5.2.1 EFT benchmarks with corresponding simplified models

If a simplified model can be mapped to a given EFT, then the model's high-mediator-mass limit will converge to the EFT. Numerically, for 14 TeV studies, we have determined that to fully reproduce the kinematics of a contact interaction and have no remaining dependence on the presence of a resonance that is as narrow as the choice made in Section 2.1.2 ($g_q = 0.25$ and $g_{\text{DM}} = 1$), the mediator mass needs to be at least 10 TeV. A comparison of the main kinematic variables for the s -channel vector mediator model with a width of $0.1 M_{\text{med}}$ is shown in Fig. 5.2.⁵

As already observed in Section 2.1.2, varying the DM mass changes the kinematics, both in the simplified model and in the EFT case. This can be seen in Fig. 5.3.

⁵ The use of a fixed width rather than the minimal width is exclusive of these plots.

Based on these studies, the Forum recommends experimental collaborations to deliver results for mediators with a mass of 10 TeV instead of fully simulated EFT results for each of the DM masses considered in the scan, and leave further reinterpretation to theorists. It should be checked that the high-mass mediator case for

(a) E_T (b) Center of mass energy E_{cm} 

(c) Mediator transverse momentum

(d) DM transverse momentum (leading)

(e) DM transverse momentum (sub-leading)

the simplified model is correctly implemented We therefore advise to add one grid scan point at very high mediator mass (10 TeV) to the scan, for each of the DM masses for the simplified models described in Section 2.

5.2.2 EFT benchmarks with no corresponding simplified models

Whenever a UV completion is not available, EFT results are still a source of useful information as described in Section 3.2.4. However, we can only roughly control how well the EFT approximation holds. Despite the fact that a propagator was introduced to motivate the truncation procedure for s -channel models, the prescription

(f) E_T , D5 operator(g) Invariant mass of the two WIMPs $m_{\chi\chi}$, D5 operator(f) E_T , simplified model(g) Invariant mass of the two WIMPs $m_{\chi\chi}$, simplified model

from Sec. 5.2.1 depends upon the simplified model to derive the energy scaling that is used for the comparison with the momentum transfer. The simple fact remains that the effective coupling of the operator – g/Λ^n – should not allow momentum flow $Q > \Lambda$ or $g > 4\pi$. Given our ignorance of the actual kinematics, the truncation procedure recommended for this purpose is the one described in Section 5.1.2, as it is independent from any UV completion details.

Because there is no UV completion, the parameter M_{cut} can be treated more freely than an explicit function of g and Λ . It makes sense to choose M_{cut} such that we identify the transition region where the EFT stops being a good description of UV complete theories. This can be done using the ratio R , which is defined as the fraction of events for which $\hat{s} > M_{\text{cut}}^2$. For large values of M_{cut} , no events are thrown away in the truncation procedure, and $R = 1$. As M_{cut} becomes smaller, eventually all events are thrown away in the truncation procedure, i.e. $R = 0$, and the EFT gives no exclusion limits for the chosen acceptance.

We propose a rough scan over M_{cut} , such that we find the values of M_{cut} for which R ranges from 0.1 to 1. The analysis can then perform a scan over several values of M_{cut} , and show the truncated limit for each one of them alongside the naive limit corresponding to $R = 1$.

Figure 5.3: Comparison of the kinematic distributions for a narrow s -channel mediator, at generator level for a jet+ E_T signature, for varying DM masses.

Evaluation of signal theoretical uncertainties

A comprehensive and careful assessment of theoretical uncertainties plays in general a more important role for the background estimations (especially when their evaluation is non-entirely data-driven) than it does for signal simulations. Nevertheless, also for signal samples theoretical uncertainties are relevant, and may become even dominant in certain regions of phase space.

In this chapter, we provide technical details on how theoretical systematic uncertainties can be assessed for events generated with POWHEG and MADGRAPH5_AMC@NLO.

6.1 POWHEG

When using POWHEG [FNO07, ANOR10, Nas04], it is possible to study scale and PDF errors for the dark matter signals. A fast reweighting machinery is available in POWHEG-BOX that allows one to add, after each event, new weights according to different scale or PDF choices, without the need to regenerate all the events from scratch.

To enable this possibility, the variable `storeinfo_rwgt` should be set to 1 in the POWHEG input file when the events are generated for the first time¹. After each event, a line starting with

```
#rwgt
```

is appended, containing the necessary information to generate extra weights. In order to obtain new weights, corresponding to different PDFs or scale choice, after an event file has been generated, a line

```
compute_rwgt 1
```

should be added in the input file along with the change in parameters that is desired. For instance, `renscfact` and `facscfact` allow one to study scale variations on the renormalization and factorization scales around a central value. By running the program again, a new event file will be generated, named `<OriginalName>-rwgt.lhe`, with one more line at the end of each event of the form

```
#new weight,renfact,facfact,pdf1,pdf2
```

followed by five numbers and a character string. The first of these numbers is the weight of that event with the new parameters chosen. By running in sequence the program in the reweighting mode,

¹ Notice that even if the variable is not present, by default it is set to 1.

several weights can be added on the same file. Two remarks are in order.

- The file with new weights is always named `<OriginalName>-rwgt.lhe` hence care has to be taken to save it as `<OriginalName>.lhe` before each iteration of the reweighting procedure.
- Due to the complexity of the environment where the program is likely to be run, it is strongly suggested as a self-consistency check that the first reweighting is done keeping the initial parameters. If the new weights are not exactly the same as the original ones, then some inconsistency must have happened, or some file was probably corrupted.

It is possible to also have weights written in the version 3 Les Houches format. To do so, in the original run, at least the token `lhrwgt_id 'ID'` must be present. The reweighting procedure is the same as described above, but now each new run can be tagged by using a different value for the `lhrwgt_id` keyword. After each event, the following lines will appear:

```
<rwgt>
<wgt id='ID'>
<wgt id='ID1'>
</rwgt>
```

A more detailed explanation of what went into the computation of every single weight can be included in the `<header>` section of the event file by adding/changing the line

```
lhrwgt_descr 'some info'
```

in the input card, before each “reweighting” run is performed. Other useful keywords to group together different weights are `lhrwgt_group_name` and `lhrwgt_group_combine`.

More detailed information can be obtained by inspecting the document in `/Docs/V2-paper.pdf` under the common POWHEG-BOX-v2 directory.

6.2 *The SysCalc package*

SysCALC is a post-processing package for parton-level events as obtained from leading-order calculations in MADGRAPH5_AMC@NLO. It can associate to each event a series of weights corresponding to the evaluation of a certain class of theoretical uncertainties. The event files in input and output are compliant with the Les Houches v3 format. For NLO calculations, PDF and scale uncertainties are instead evaluated automatically by setting corresponding instructions in the `run_card.dat` and no post-processing is needed (or possible).

The requirements of the package as inputs are :

- A systematics file (which can be generated by MadGraph 5 v. 1.6.0 or later) [A^{+14b} , AHM^{+11}].
- The Pythia-PGS package (v. 2.2.0 or later) [SMS_{06}]. This is needed only in the case of matching scales variations.
- The availability of LHAPDF5 [WBG_{05}].
- A configuration file (i.e. a text file) specifying the parameters to be varied.

SysCALC supports all leading order computations generated in MADGRAPH5_AMC@NLO including fixed-order computation and matched-merged computation performed in the MLM scheme [$MMPT_{07}$]. MADGRAPH5_AMC@NLO stores additional information inside the event in order to have access to all the information required to compute the convolution of the PDFs with the matrix element for the various supported systematics.

Below follows an example configuration file which could serve as an example:

```
# Central scale factors
scalefact:
0.5 1 2
# Scale correlation
# Special value -1: all combination (N**2)
# Special value -2: only correlated variation
# Otherwise list of index N*fac_index + ren_index
# index starts at 0
scalecorrelation:
-1
#  $\alpha_s$  emission scale factors
alpsfact:
0.5 1 2
# matching scales
matchscale:
30 60 120
# PDF sets and number of members (optional)
PDF:
CT10.LHgrid 53
MSTW2008nlo68cl.LHgrid
```

Without matching/merging, SysCALC is able to compute the variation of renormalisation and factorisation scale (parameter scalefact) and the change of PDFs. The variation of the scales can be done in a correlated and/or uncorrelated way, basically following the value of the scalecorrelation parameter which can take the following values:

- -1 : to account for all N^2 combinations.
- -2 : to account only for the correlated variations.
- A set of positive values corresponding to the following entries (assuming 0.5, 1, 2 for the scalefact entry):

- 0: $\mu_F = \mu_F^{\text{orig}}/2, \mu_R = \mu_R^{\text{orig}}/2$
- 1: $\mu_F = \mu_F^{\text{orig}}/2, \mu_R = \mu_R^{\text{orig}}$
- 2: $\mu_F = \mu_F^{\text{orig}}/2, \mu_R = \mu_R^{\text{orig}} * 2$

2290 3: $\mu_F = \mu_F^{\text{orig}}, \mu_R = \mu_R^{\text{orig}}/2$
 2291 4: $\mu_F = \mu_F^{\text{orig}}, \mu_R = \mu_R^{\text{orig}}$
 2292 5: $\mu_F = \mu_F^{\text{orig}}, \mu_R = \mu_R^{\text{orig}} * 2$
 2293 6: $\mu_F = \mu_F^{\text{orig}} * 2, \mu_R = \mu_R^{\text{orig}}/2$
 2294 7: $\mu_F = \mu_F^{\text{orig}} * 2, \mu_R = \mu_R^{\text{orig}}$
 2295 8: $\mu_F = \mu_F^{\text{orig}} * 2, \mu_R = \mu_R^{\text{orig}} * 2$

Without correlation, the weight associated to the renormalisation scale is the following:

$$\mathcal{W}_{\text{new}}^{\mu_R} = \frac{\alpha_S^N(\Delta * \mu_R)}{\alpha_S^N(\mu_R)} * \mathcal{W}_{\text{orig}}, \quad (6.1)$$

where Δ is the scale variation considered, $\mathcal{W}_{\text{orig}}$ and \mathcal{W}_{new} are respectively the original/new weights associated to the event. N is the power in the strong coupling for the associated event (interference is not taken account on an event by event basis). The weight associated to the scaling of the factorisation scale is:

$$\mathcal{W}_{\text{new}}^{\mu_F} = \frac{f_{1,\text{orig}}(x_1, \Delta * \mu_F) * f_{2,\text{orig}}(x_2, \Delta * \mu_F)}{f_{1,\text{orig}}(x_1, \mu_F) * f_{2,\text{orig}}(x_2, \mu_F)} * \mathcal{W}_{\text{orig}}, \quad (6.2)$$

2296 where $f_{i,\text{orig}}$ are the probabilities from the original PDF set asso-
 2297 ciated to the incoming partons, which hold a proton momentum
 2298 fraction x_1 and x_2 for the first and second beam respectively.

The variations for the PDF are given by the corresponding weights associated to the new PDF sets:

$$\mathcal{W}_{\text{new}}^{\text{PDF}} = \frac{f_{1,\text{new}}(x_1, \mu_F) * f_{2,\text{new}}(x_2, \mu_F)}{f_{1,\text{orig}}(x_1, \mu_F) * f_{2,\text{orig}}(x_2, \mu_F)} * \mathcal{W}_{\text{orig}}, \quad (6.3)$$

2299 where $f_{i,\text{new}}$ is the new PDF probability associated to parton i .

2300 In presence of matching, MADGRAPH5_AMC@NLO associates
 2301 one history of radiation (initial and/or final state radiation) ob-
 2302 tained by a k_T clustering algorithm, and calculates α_s at each vertex
 2303 of the history to a scale given by the aforementioned clustering
 2304 algorithm. Furthermore, MADGRAPH5_AMC@NLO reweights
 2305 the PDF in a fashion similar to what a parton shower would do.
 2306 SysCALC can perform the associated re-weighting (parameter
 2307 `alpsfact`) by dividing and multiplying by the associated factor.

For each step in the history of the radiation (associated to a scale $\mu_i = k_{T,i}$), this corresponds to the following expression for a Final State Radiation (FSR):

$$\mathcal{W}_{\text{new}}^{\text{FSR}} = \frac{\alpha_s(\Delta * \mu_i)}{\alpha_s(\mu_i)} * \mathcal{W}_{\text{orig}}, \quad (6.4)$$

and to the following expression for Initial State Radiation (ISR), associated to a scale μ_i and fraction of energy x_i :

$$\mathcal{W}_{\text{new}}^{\text{ISR}} = \frac{\alpha_s(\Delta * \mu_i)}{\alpha_s(\mu_i)} \frac{\frac{f_a(x_i, \Delta * \mu_i)}{f_b(x_i, \Delta * \mu_{i+1})}}{\frac{f_a(x_i, \mu_i)}{f_b(x_i, \mu_{i+1})}} * \mathcal{W}_{\text{orig}}, \quad (6.5)$$

where μ_{i+1} is the scale of the next step in the (initial state) history of radiation.

SysCALC can include the weight associated to different merging scales in the MLM matching/merging mechanism (for output of the pythia6 package or pythia-pgs package).

In that case, the parton shower does not veto any event according to the MLM algorithm, although in the output file the scale of the first emission is retained. Having this information, SysCALC can test each value of the specified matching scales under the matchscale parameter block. SysCALC will then test for each of the values specified in the parameter matchscale if the event passes the MLM criteria or not. If it does not, then a zero weight is associated to the event, while if it does, then a weight 1 is kept. As a reminder, those weights are the equivalent of having a (approximate) Sudakov form-factor and removing at the same time the double counting between the events belonging to different multiplicities.

Finally, we give an example of the SysCALC output which follows the LHEF v3 format. The following block appears in the header of the output file:

```
<header>
  <initrwgt>
    <weightgroup type="Central scale variation" combine="envelope">
      <weight id="1"> mur=0.5 muf=0.5 </weight>
      <weight id="2"> mur=1 muf=0.5 </weight>
      <weight id="3"> mur=2 muf=0.5 </weight>
      <weight id="4"> mur=0.5 muf=1 </weight>
      <weight id="5"> mur=1 muf=1 </weight>
      <weight id="6"> mur=2 muf=1 </weight>
      <weight id="7"> mur=0.5 muf=2 </weight>
      <weight id="8"> mur=1 muf=2 </weight>
      <weight id="9"> mur=2 muf=2 </weight>
    </weightgroup>
    <weightgroup type="Emission scale variation" combine="envelope">
      <weight id="10"> alpsfact=0.5</weight>
      <weight id="11"> alpsfact=1</weight>
      <weight id="12"> alpsfact=2</weight>
    </weightgroup>
    <weightgroup type="CT10nlo.LHgrid" combine="hessian">
      <weight id="13">Member 0</weight>
      <weight id="14">Member 1</weight>
      <weight id="15">Member 2</weight>
      <weight id="16">Member 3</weight>
      ...
      <weight id="65">Member 52</weight>
    </weightgroup>
  </initrwgt>
</header>
```

For each event, the weights are then written as follows:

```
<rwgt>
  <wgt id="1">83214.7</wgt>
  <wgt id="2">61460</wgt>
  <wgt id="3">47241.9</wgt>
  <wgt id="4">101374</wgt>
  ...
  <wgt id="64">34893.5</wgt>
  <wgt id="65">41277</wgt>
</rwgt>
```

Conclusions

The conclusions will contain a summary of the recommendation from the ATLAS/CMS DM Forum report, together with the summary table below.

Benchmark models for ATLAS and CMS Run-2 DM searches

Table 6.1: Summary table for recommended benchmark models and their implementation.

They will also include a series of points to be developed further beyond the timescale of the Forum. These points will be discussed at the meeting that marks the conclusion of the works of the Forum, to be held during the week of June 10th.

A

Appendix: Additional models for Dark Matter searches

A.1 Models with a single top–quark + \cancel{E}_T

Many different theories predict final states with a single top and associated missing transverse momentum (monotop), some of them including dark matter candidates. A simplified model encompassing the processes leading to this phenomenology is described in Refs. [AFM11, AAB⁺14, BCDF15], and is adopted as one of the benchmarks for Run 2 LHC searches.

The simplified model is constructed by imposing that the model Lagrangian respects the electroweak $SU(2)_L \times U(1)_Y$ gauge symmetry and by requiring minimality in terms of new states to supplement to the Standard Model fields. As a result, two monotop production mechanisms are possible. In the first case, the monotop system is constituted by an invisible (or long-lived with respect to detector distances) fermion χ and a top quark. It is produced as shown in the diagram of A.1 (a) where a colored resonance φ lying in the triplet representation of $SU(3)_C$ decays into a top quark and a χ particle. In the second production mode, the monotop state is made of a top quark and a vector state V connected to a hidden sector so that it could decay invisibly into, e.g., a pair of dark matter particles as studied in [BCDF15]. The production proceeds via flavor-changing neutral interactions of the top quark with a quark of the first or second generation and the invisible V boson (see the diagrams of A.1 (b) and (c)).

RESONANT PRODUCTION

In this case, a colored 2/3-charged scalar (φ) is produced and decays into a top quark and a spin-1/2 invisible particle, χ . The dynamics of the new sector is described by the following Lagrangian:

$$\mathcal{L} = \left[\varphi \bar{d}^c \left[a_{SR}^q + b_{SR}^q \gamma_5 \right] d + \varphi \bar{u} \left[a_{SR}^{1/2} + b_{SR}^{1/2} \gamma_5 \right] \chi + \text{h.c.} \right], \quad (\text{A.1})$$

where u (d) stands for any up-type (down-type) quark, the notation SR refers to the monotop production mechanism via a scalar resonance and all flavor and color indices are understood for clarity.

In the notation of [AAB⁺14], the couplings of the new colored fields to down-type quarks are embedded into the 3×3 antisym-

Figure A.1: Feynman diagrams of leading order processes leading to monotop events: production of a colored scalar resonance ϕ decaying into a top quark and a spin-1/2 fermion χ (a), s - (b) and t -channel (c) non resonant production of a top quark in association with a spin-1 boson V decaying invisibly.

metric matrices a_{SR}^q (scalar couplings) and b_{SR}^q (pseudoscalar couplings) while those to the new fermion χ and one single up-type quark are given by the three-component vectors $a_{SR}^{1/2}$ and $b_{SR}^{1/2}$ in flavor space.

Under the form of Eq. (A.1), the Lagrangian is the one introduced in the original monotop search proposal [AFM11]. It has been used by the CMS collaboration for Run I analyses after neglecting all pseudoscalar components of the couplings and adding the vector resonance case for which minimality requirements are difficult to accommodate [CMS15b]. In contrast, the study of Ref. [BCDF15] has imposed electroweak gauge invariance and required minimality. This enforces all new couplings to be right-handed so that

$$a_{SR}^{1/2} = b_{SR}^{1/2} = \frac{1}{2} y_s^* \quad \text{and} \quad a_{SR}^q = b_{SR}^q = \frac{1}{2} \lambda_s, \quad (\text{A.2})$$

where the objects y_s and λ_s are a tridimensional vector and a 3×3 matrix in flavor space respectively. This class of scenarios is the one that has been adopted by the ATLAS collaboration for its Run I monotop searches [ATL15b] and will be considered by both collaborations for Run II analyses.

The resulting model can be likened to the MSSM with an R -parity violating of a top squark to the Standard Model down-type quarks and an R -parity conserving interaction of a top quark and a top-squark to a neutralino.

NON-RESONANT PRODUCTION

For non-resonant monotop production, the monotop state is produced via flavor-changing neutral interactions of the top quark, a lighter up-type quark and a new invisible vector particle V . This

is the only case considered, as having a new scalar would involve in particular a mixing with the SM Higgs boson and therefore a larger number of free parameters. The Lagrangian describing the dynamics of this non-resonant monotop production case is:

$$\mathcal{L} = \left[V_\mu \bar{u} \gamma^\mu \left[a_{FC}^1 + b_{FC}^1 \gamma_5 \right] u + \text{h.c.} \right], \quad (\text{A.3})$$

where the flavor and color indices are again understood for clarity. The strength of the interactions among these two states and a pair of up-type quarks is modeled via two 3×3 matrices in flavor space a_{FC}^1 for the vector couplings and b_{FC}^1 for the axial vector couplings, the FC subscript referring to the flavor-changing neutral monotop production mode and the (1) superscript to the vectorial nature of the invisible particle.

As for the resonant case, the Lagrangian of Eq. (A.3) is the one that has been used by CMS after reintroducing the scalar option for the invisible state and neglecting all pseudoscalar interactions [CMS15b]. As already mentioned, a simplified setup motivated by gauge invariance and minimality has been preferred so that, as shown in Ref. [BCDF15], we impose all interactions to involve right-handed quarks only,

$$a_{FC}^1 = b_{FC}^1 = \frac{1}{2} a_R \quad (\text{A.4})$$

where a_R denotes a 3×3 matrix in flavor space. This implies the vector field to be an $SU(2)_L$ singlet.

MODEL PARAMETERS AND ASSUMPTIONS

The models considered as benchmarks for the first LHC searches contain further assumptions in terms of the flavor structure of the model with respect to the Lagrangians of the previous subsection. In order to have an observable monotop signature at the LHC, the Lagrangians introduced above must include not too small couplings of the new particles to first and second generation quarks. For simplicity, we assumed that only channels enhanced by parton density effects will be considered, so that we fix

$$\begin{aligned} (a_R)_{13} &= (a_R)_{31} = a, \\ (\lambda_s)_{12} &= -(\lambda_s)_{21} = \lambda \quad \text{and} \quad (y_s)_3 = y, \end{aligned} \quad (\text{A.5})$$

all other elements of the matrices and vectors above being set to zero.

To do (??)

IMPLEMENTATION In order to allow one for the Monte Carlo simulation of events relevant for the monotop production cases described above, we consider the Lagrangian

$$\mathcal{L} = \left[a V_\mu \bar{u} \gamma^\mu P_R \gamma_5 t + \lambda \phi \bar{d}^c P_R s + y \phi \bar{\chi} P_R t + \text{h.c.} \right], \quad (\text{A.6})$$

where P_R stands for the right-handed chirality projector and the new physics couplings are defined by the three parameters a , λ and

y . We additionally include a coupling of the invisible vector boson V to a dark sector (represented by a fermion ψ) whose strength can be controlled through a parameter g_{DM} ,

$$\mathcal{L} = g_{DM} V_\mu \bar{\psi} \gamma^\mu \psi . \quad (\text{A.7})$$

This ensures the option to make the V -boson effectively invisible by tuning g_{DM} respectively to a . We implement the entire model in the FEYNRULES package [ACD⁺14] so that the model can be exported to a UFO library [DDF⁺12] to be linked to MADGRAPH5_AMC@NLO [AFF⁺14] for event generation, following the approach outlined in [CdAD⁺11].

A.1.1 Parameter scan

Under all the assumptions of the previous sections, the parameter space of the resonant model is defined by four quantities, namely the mass of the new scalar field φ , the mass of the invisible fermion χ and the strengths of the interactions of the scalar resonance with the monotop system y and with down-type quarks λ . One of both coupling parameters could however be traded with the width of the resonance.

The parameter space of the non-resonant model is defined by two parameters, namely the mass of the invisible state V and its flavor-changing neutral coupling to the up-type quarks a_R .

In the case of the non-resonant model, the invisible vector is connected to a hidden sector that could be, in its simplest form, parameterized by a new fermion [BCDF15]. This has effects on the width of the invisible V state.

A consensus between the ATLAS and CMS collaborations has been reached in the case of non-resonant monotop production. The results have been described above. In contrast, discussions in the context of resonant monotop production are still on-going. The related parameter space contains four parameters and must thus be further simplified for practical purposes. Several options are possible and a choice necessitates additional studies that will be achieved in a near future.

It has been verified that the kinematics do not depend on the width of the invisible state in the case where this width is at most 10% of the V -mass. This is illustrated in Figures A.2 and A.3, where we respectively show the invariant-mass and transverse-momentum spectra of the V -boson when it decays into a top-up final state and for different V -boson masses. The results are however independent of the visible or invisible decay modes as we are only concerned with the kinematical properties of the invisible state.

A.1.2 Single Top Models

Card files for MADGRAPH5_AMC@NLO are provided on the Forum SVN repository [For15e] and correspond to the Lagrangian

Figure A.2: Distributions of the invariant mass of the V boson in the case of the process $pp \rightarrow tV \rightarrow t(t\bar{u} + \text{c.c.})$. We have imposed that the V -boson is produced on-shell and have chosen its mass to be $m_V = 200, 600$ and 1000 GeV (left, central and right panels). Moreover, we have considered three possible cases for the total width of the V -boson, which has been fixed to 0.61% , 0.1% and 10% of the mass.

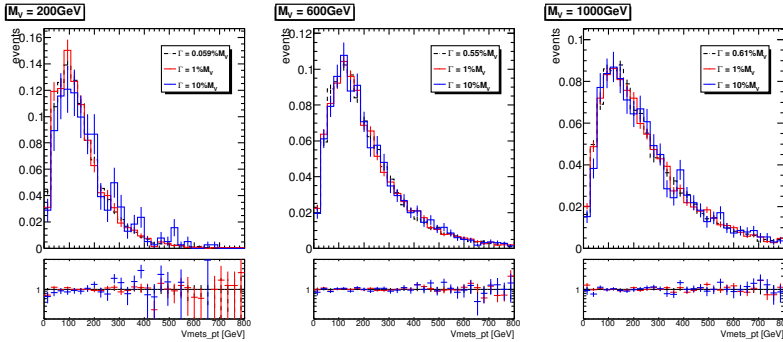

Figure A.3: Same as Figure A.2 in the case of the transverse-momentum distribution of the V -boson.

that has been implemented in `FeynRules`. Each coupling constant of the model can be set via the block `COUPX` of the parameter card. Its entries 1, 2 and 3 respectively correspond to the monotop-relevant parameters a , λ and y , while the width (and in particular the invisible partial width) of the V -boson can be tuned *via* the g_{DM} parameter to given in the entry 10 of the `COUPX` block.

The masses of the particles are set in the `MASS` block of the parameter card, the PDG codes of the new states being 32 (the vector state V), 1000006 (the ϕ colored resonance), 1000022 (the invisible fermion χ) and 1000023 (the fermion ψ connecting the V state to the dark sector). The width of the new vector has to be computed from all open tree-level decays (after fixing g_{DM} to a large value and setting the relevant entry to `Auto` in the `DECAY` block of the parameter card), while the way to calculate the width of the resonance ϕ is under discussion by both the ATLAS and CMS collaborations. The χ and ψ fermions are taken stable so that their width vanishes.

A.2 Further $W + \cancel{E}_T$ models with possible cross-section enhancements

As pointed out in Ref. [BCD⁺15], the mono- W signature can probe the iso-spin violating interactions of dark matter with quarks. The relevant operator after the electroweak symmetry breaking is

$$\frac{1}{\Lambda^2} \bar{\chi} \gamma_\mu \chi (\bar{u}_L \gamma^\mu u_L + \xi \bar{d}_L \gamma^\mu d_L) . \quad (\text{A.8})$$

Here, we only keep the left-handed quarks because the right-handed quarks do not radiate a W -gauge boson from the weak interaction. As the LHC constrains the cutoff to higher values, it is also important to know the corresponding operators before the electroweak symmetry. At the dimension-six level, the following operator

$$\frac{c_6}{\Lambda^2} \bar{\chi} \gamma_\mu \chi \bar{Q}_L \gamma^\mu Q_L \quad (\text{A.9})$$

conserves iso-spin and provides us $\xi = 1$ [BCD⁺15]. At the dimension-eight level, new operators appear to induce iso-spin violation and can be

$$\frac{c_8^d}{\Lambda^4} \bar{\chi} \gamma_\mu \chi (H \bar{Q}_L) \gamma^\mu (Q_L H^\dagger) + \frac{c_8^u}{\Lambda^4} \bar{\chi} \gamma_\mu \chi (\tilde{H} \bar{Q}_L) \gamma^\mu (Q_L \tilde{H}^\dagger). \quad (\text{A.10})$$

After inputting the vacuum expectation value of the Higgs field, we have

$$\xi = \frac{c_6 + c_8^d v_{\text{EW}}^2 / 2\Lambda^2}{c_6 + c_8^u v_{\text{EW}}^2 / 2\Lambda^2}. \quad (\text{A.11})$$

For a nonzero c_6 and $v_{\text{EW}} \ll \Lambda$, the iso-spin violation effects are suppressed. On the other hand, the values of c_6 , c_8^d and c_8^u depend on the UV-models.

There is one possible UV-model to obtain a zero value for c_6 and non-zero values for c_8^d and c_8^u . One can have the dark matter and the SM Higgs field charged under a new $U(1)'$ symmetry. There is a small mass mixing between SM Z -boson and the new Z' with a mixing angle of $\mathcal{O}(v_{\text{EW}}^2 / M_{Z'}^2)$. After integrating out Z' , one has different effective dark matter couplings to u_L and d_L fields, which are proportional to their couplings to the Z boson. For this model, we have $c_6 = 0$ and

$$\xi = \frac{-\frac{1}{2} + \frac{1}{3} \sin^2 \theta_W}{\frac{1}{2} - \frac{2}{3} \sin^2 \theta_W} \approx -2.7 \quad (\text{A.12})$$

and order of unity.

A.3 Simplified model corresponding to dimension-5 EFT operator

As an example of a simplified model corresponding to the dimension-5 EFT operator described in Section 3.2, we consider a Higgs portal with a scalar mediator. Models of this kind are among the most concise versions of simplified models that produce couplings of Dark Matter to pairs of gauge-bosons. Scalar fields may couple directly to pairs of electroweak gauge bosons, but must carry part of the electroweak vacuum expectation value. One may thus consider a simple model where Dark Matter couples to a scalar singlet mediator, which mixes with the fields in the Higgs sector.

$$L \subset m_s S^2 + \lambda S^2 H^2 + \lambda' S H^2 + y S \chi \bar{\chi} \quad (\text{A.13})$$

Where H is a field in the Higgs sector that contains part of the electroweak vacuum expectation value, S is a heavy scalar singlet

and χ is a Dark Matter field. There is then an s -channel diagram where DM pairs couple to the singlet field S , which then mixes with a Higgs-sector field, and couples to W and Z bosons. This diagram contains 2 insertions of EW symmetry breaking fields, corresponding in form to the effective dimension-5 operator in Section 3.2.1.

A.4 Inert 2HDM Model

For most of the simplified models included in this report, the mass of the mediator and couplings/width are non-trivial parameters of the model. In these scenarios, we remain agnostic about the theory behind the dark matter sector and try to parameterize it in simple terms.

We have not addressed how to extend the simplified models to realistic and viable models which are consistent with the symmetries of the Standard Model. Simplified models often violate gauge invariance which is a crucial principle for building a consistent BSM model which incorporates SM together with new physics. For example, with a new heavy gauge vector boson mediating DM interactions, one needs not just the dark matter and its mediator, but also a mechanism which provides mass to this mediator in a gauge invariant way.

Considering both the simplified model and other elements necessary for a consistent theory is a next logical step. The authors of [BCI⁺] term these Minimal Consistent Dark Matter (MCDM) models. MCDM models are at the same time still toy models that can be easily incorporated into a bigger BSM model and explored via complementary constraints from collider and direct/indirect DM search experiments as well as relic density constraints. We discuss this model here both on its own merits and as an example of the flexibility of the simplified model approach.

The idea of an inert Two-Higgs Doublet Model (i2HDM) was introduced more than 30 years ago in [DM78, LHNOT07, DS09, GHS13, BCI⁺]. It is an extension of the SM with a second scalar doublet ϕ_2 with no direct coupling to fermions. This doublet has a discrete Z_2 symmetry, under which ϕ_2 is odd and all the other fields are even. The Lagrangian of the odd sector is,

$$\mathcal{L} = \frac{1}{2}(D_\mu \phi_2)^2 - V(\phi_1, \phi_2) \quad (\text{A.14})$$

with the potential V containing mass terms and $\phi_1 - \phi_2$ interactions:

$$\begin{aligned} V = & -m_1^2(\phi_1^\dagger \phi_1) - m_2^2(\phi_2^\dagger \phi_2) + \lambda_1(\phi_1^\dagger \phi_1)^2 + \lambda_2(\phi_2^\dagger \phi_2)^2 \\ & + \lambda_3(\phi_2^\dagger \phi_2)(\phi_1^\dagger \phi_1) + \lambda_4(\phi_2^\dagger \phi_1)(\phi_1^\dagger \phi_2) + \frac{\lambda_5}{2} [(\phi_1^\dagger \phi_2)^2 + (\phi_2^\dagger \phi_1)^2], \end{aligned} \quad (\text{A.15})$$

where ϕ_1 and ϕ_2 are SM and inert Higgs doublets respectively carrying the same hypercharge. These doublets can be parameter-

ized as

$$\phi_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + H \end{pmatrix} \quad \phi_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}h^+ \\ h_1 + ih_2 \end{pmatrix} \quad (\text{A.16})$$

In addition to the SM, i2HDM brings four more degrees of freedom coming from the inert doublet in the form of Z_2 -odd charged scalar h^\pm and two neutral Z_2 -odd scalars h_1 and h_2 . The lightest neutral scalar, h_1 is identified as the dark matter candidate. The i2HDM model has been explored at the phenomenological level from the perspective of collider DM searches [BPtVo1, AHTo8, ATYY14, BCI⁺]. This model could produce \cancel{E}_T +jet, Z, and Higgs as well as \cancel{E}_T +VBF signatures at the LHC (see Figs. A.4–A.9).

Figure A.4: Feynman diagrams for $gg \rightarrow h_1 h_1 + g$ process contributing to mono-jet signature, adapted from [BCI⁺].

Figure A.5: Feynman diagrams for $q\bar{q} \rightarrow h_1 h_2 + g$ ($gq \rightarrow h_1 h_2 + q$) process contributing to mono-jet signature, adapted from [BCI⁺].

Figure A.6: Feynman diagrams for $q\bar{q} \rightarrow h_1 h_1 + Z$ process contributing to mono-Z signature, adapted from [BCI⁺].

An experimental analysis of the parameter space has recently been performed in Ref. [BCI⁺]. The authors of that study have implemented the model in CalcHEP and micrOMEGAs and propose a set of benchmark points (Table. A.1). Though the overall parameter space of i2HDM is 5-dimensional, the parameter space relevant to a specific LHC signature is only 1-2 dimensional. In the mono-jet case, one can use two separate simplified models, a $gg \rightarrow h_1 h_1 + g$ process (via Higgs mediator) and a $q\bar{q} \rightarrow h_1 h_2 + g$ ($gq \rightarrow h_1 h_2 + q$) process (using Z-boson mediator) to capture the physics relevant to the search.

Figure A.7: Feynman diagrams for $gg \rightarrow h_1 h_1 + H$ process contributing to mono-Higgs signature, adapted from [BCI⁺].

Figure A.8: Feynman diagrams for $q\bar{q} \rightarrow h_1 h_2 + H$ process contributing to mono-Higgs signature, adapted from [BCI⁺].

Figure A.9: Diagrams for $qq \rightarrow qq h_1 h_1$ DM production in vector boson fusion process, adapted from [BCI⁺].

Benchmark	1	2	3	4	5
M_{h_1} (GeV)	45	53	66	82	120
M_{h_2} (GeV)	55	189	77	89	140
$M_{h_{\pm}}$ (GeV)	130	182	122	150	200
λ_2	0.8	1.0	1.1	0.9	1.0
λ_{345}	-0.010	-0.024	+0.022	-0.090	-0.100
Ω_h^2	1.1×10^{-1}	8.1×10^{-2}	9.9×10^{-2}	1.5×10^{-2}	2.1×10^{-3}
σ_{SI} (fb)	1.9×10^{-7}	7.9×10^{-7}	4.2×10^{-7}	4.5×10^{-7}	2.6×10^{-6}
σ_{LHC} (fb)	1.7×10^2	7.7×10^2	4.3×10^{-2}	1.2×10^{-1}	2.3×10^{-2}

Table A.1: Five benchmarks for i2HDM in $(M_{h_1}, M_{h_2}, M_{h_{\pm}}, \lambda_2, \lambda_{345})$ parameter space. We also present the corresponding relic density (Ω_{h^2}), the spin-independent cross section for DM scattering on the proton, and the LHC cross section at 13 TeV for mono-jet process $pp \rightarrow h_1, h_1 + jet$ for $p_T^{jet} > 100$ GeV cut.

B

Appendix: Presentation of experimental results for reinterpretation

We suggest the following to collider searches, when presenting results from the recommended benchmarks:

- Provide limits in collider language, on fundamental parameters of interaction: couplings and masses of particles in simplified model.
- Translate limits to non-collider language, for a range of assumptions in order to convey a rough idea of the range of possibilities. The details of this point are left for work beyond the scope of this Forum.
- Provide all necessary material for theorists to reinterpret simplified model results as building blocks for more complete models (e.g. signal cutflows, acceptances, etc). This point is detailed further in this appendix.
- As detailed in [KAM⁺12], model-independent results in terms of limits on cross-section times acceptance of new phenomena should be provided for all cases, but especially when EFTs are employed as benchmarks.

Along with the design of new searches to hunt for new physics at the LHC, it is important to consider information needed in order to reinterpret the searches outside of the collaborations. The following is a non-exhaustive list of recommendations in order to make reinterpretation easier and faster. This appendix details considerations for reimplementation of the analysis as well as for using the simplified model results directly given by the collaborations.

One of the important developments in recent years is an active development of the analyses recasting codes [DFK⁺15, CDFW14, KSTR15, CY11, KPSW]. The aim of these codes is to provide a public library of reimplemented and validated LHC analyses. Such libraries can then be used to analyze validity of a BSM scenario in a systematic and effective manner. The availability of public libraries further facilitates a unified framework and can lead to an organized and central structure to preserve LHC information in a long run.

In order to be able to develop such codes, it is important to get complete and systematic information from the collaborations.

- **Data digitization:** Availability of digitized data is one of the primary requirement. All information given by collaborations in the form of plots should be made available in a digitized format. Platforms such as HepData can be used in order to maintain a centralized manner. In case when HepData can not be used, digitized data can be provided via analyses twiki pages. This information primarily includes expected and observed exclusion lines along with their $\pm 1\sigma$ uncertainty, expected and observed upper limits in case of simplified models, efficiency maps and all kinematic distributions as reported in the analysis. Units should be clearly specified. If the digitized figures are made available as a C macro or a ROOT file, the names of the objects should be clearly identifiable e.g. expected upper limits of a particular topology/model given as a ROOT file can be labeled as KEY: TH2D ExpectedUpperLimit;1. Furthermore, these digitized files can potentially contain more information (larger axes ranges) than displayed on the plot. This will help facilitate understand what happens beyond the limits displayed in the plot, e.g. a distribution for number of jets can be artificially limited to a point in the plot (for the purpose of clarity of figure), however, this artificial limit leads to a sharp cutoff in the plot. While validating the analysis it is often necessary to compare the distributions beyond such artificial limits, having this information digitized will be of a great help in such cases.

B.1 Reimplementing analyses

This section lists information necessary in order to reimplement an analysis. Analysis reimplementation usually consists of several stages. Usually, one starts with reading the analysis note carefully, following which the preselection and event selection cuts are identified. These are then mimicked using a code typically written in C++. The detector simulation is carried out by using public detector simulation software e.g. Delphes [dF⁺14]. The resulting ROOT file is then analyzed using the C++ code written in the previous step.

- **Analysis documentation:** The collaborations should provide a cutflow table with every analysis, such a cutflow table will naturally define the order of cuts implemented in an analysis. There are several preselection criteria which can not be easily simulated in phenomenology, e.g. MET cleaning. Numbers should be provided after such cuts so that theorists can rescale their number of events in order to account for such cuts. Efficiencies of several reconstructed objects are given as an input to detector simulation software like Delphes. It is thus very useful to get parametrized efficiencies for reconstructed objects (as a function of the rapidity η and/or transverse momentum p_T), along with the working

points at which they were evaluated (e.g. loose, tight selection).
Object definitions should be clearly identifiable.

- **Validation:** Validation corresponds to re-deriving the results as given by collaborations in order to verify that the implementation of the analysis is correct. Usually most of the bug catching takes place in the phase of validation. The following items are necessary in order to recreate the results.
 - Monte Carlo generators: Monte Carlo generators along with the exact versions used to produce the event files should be listed.
 - Production cross sections: The order of production cross sections (e.g. LO,NLO,NLL) as well as the codes which were used to compute them should be provided. A table of reference cross sections for several values of particle masses such as ones provided by SUSY cross section working group will be highly appreciated.
 - Process Generation: Details of the generated process, detailing number of additional partons generated.
 - Availability of the LHE files: selected LHE files (detailing at least a few events if not the entire file) corresponding to the benchmarks listed in the analysis should be made available in order to cross check process generation. Experimental collaborations may generate events on-the-fly without saving the intermediate LHE file; we advocate that the cross-check of process generation is straight-forward if this information is present, so we encourage the generation of a few selected benchmark points allowing for a LHE file to be saved. For models concerning SUSY, corresponding SLHA files of benchmark files should also be details. Special attention should be paid to list the parameters which change the production cross section or kinematics of the process e.g. mixing angles.
 - Process cards: Process cards includes PDF choices, details of matching algorithms and scales and details of process generation. If process cards are not available, above items should be clearly identified.
 - model files: For models which are not already implemented in MADGRAPH5_AMC@NLO, availability of the corresponding model files in UFO format [DDF⁺12] is highly desired. It details the exact notation used in the model and hence sets up a complete framework. In case MADGRAPH5_AMC@NLO is not used, enough information should be provided in order to clearly identify the underlying model used for interpretations.
- **Limit setting:** Detailed description of the likelihood used in order to derive the limits should be given, this can contain statistical procedure within the analysis text itself, however direct availability of the limit setting code as a workspace in RooStats or HistFitter [BBC⁺15] is highly desirable.

- **Binned backgrounds:** For analyses using techniques such as sliding windows or an unbinned technique, the Standard Model backgrounds should be given in the form of bins. These backgrounds can then be interpolated.
- **Recast code:** Finally, the collaborations can provide an analysis code directly implemented in one of the public recasting codes detailed above. Such codes can be published via INSPIRE in order to track the versioning and citations.

B.2 Simplified model interpretations

The analyses almost always provide at least one simplified model interpretation along with the search results. These interpretations are simple and can be used in order to take a quick survey of viability of parameter space. Codes such as [KKL⁺14b, KKL⁺14a, PSWZ14] can make use of the simplified model results given in the form of 95% Confidence Level (CLs) upper limit or efficiency maps in order to test Beyond the Standard Model parameter space. It will thus be extremely useful if the results are given in a form as easily usable by the theory community.

- **Direct usability of the results:** The results given should be as useful as possible. For example, for a simplified model containing dark matter mass m_{DM} , mediator mass M_{med} and couplings g_{DM}, g_q it will be extremely useful to have 95% CLs upper limits on the product of couplings $\sqrt{g_{\text{DM}}g_q}$ or cross section times branching ratio as a function of $m_{\text{DM}}, M_{\text{med}}$. Limits on visible cross sections of the simplified models considered for interpretations should be made available.
- **Smooth grids:** The usage of simplified model results relies on interpolating between upper limit values. In order to facilitate the interpolation, regions where large variation of upper limits is observed should contain denser grid, if a uniform grid over the entire plane is not possible. For simplified model involving more than three parameters (two masses and product of couplings), slices of upper limits in the additional dimensions will be very useful e.g. for a simplified model involving one step cascade decay, upper limits can be provided for several values of intermediate mass in the plane of mother - daughter masses. Results with only one slice often render invalid to be used in a general model testing.
- **Availability of acceptance and efficiency maps:** Finally, acceptance and efficiency maps for all the signal regions involved in the analysis should be made available. These results are not only useful for model testing using simplified models but also to validate implementation of the analysis. Information about the most sensitive signal region as a function of masses is also very useful in order to determine the validity of approximate limit setting

2722 procedures being used by theorists (in the absence of any other
2723 sophisticated limit setting technique).

C

Appendix: Additional details and studies within the Forum

C.1 Further information for baryonic Z' Model

C.1.1 Cross-section scaling

The dependence of the cross section of the $pp \rightarrow H\chi\bar{\chi} + X$ process on $g_{hZ'Z'}$ is shown in Figure C.1. The curves have been fit to second-order polynomials, where y is the cross-section and x is the coupling $g_{hZ'Z'}$.

For $m_{\text{med}} = 100$ GeV, the fit function is

$$y = -0.12 - 3.4 \times 10^{-3}x + 2.7 \times 10^{-4}x^2$$

. For $m_{\text{med}} = 1$ TeV, the fit function is

$$y = 0.0012 - 2.4 \times 10^{-7}x + 1.5 \times 10^{-7}x^2$$

,

$$y = -0.12 - 3.4 \times 10^{-3}x + 2.7 \times 10^{-4}x^2. \quad (\text{C.1})$$

For $M_{\text{med}} = 1$ TeV, the fit function is:

$$y = 0.0012 - 2.4 \times 10^{-7}x + 1.5 \times 10^{-7}x^2. \quad (\text{C.2})$$

C.2 Minimal mediator width in s -channel exchange

Tables C.1 and C.2 give the $\Gamma_{\text{min}}/M_{\text{med}}$ ratio for the parameter grid proposed in Section 2.1 for vector and axial-vector s -channel models, respectively. The numbers range from ~ 0.02 in the off-shell Dark Matter production regime at $2m_{\text{DM}} > M_{\text{med}}$ to ~ 0.06 in the on-shell regime for heavy mediators where all coupling channels contribute.

For the parameter grid for scalar and pseudo-scalar mediator exchange in s -channel proposed in Section 2.2, the $\Gamma_{\text{min}}/M_{\text{med}}$ ratio is given in Tables C.3 and C.4, respectively. In the on-shell production regime, the ratio is ~ 0.04 . Very narrow resonances with $\Gamma_{\text{min}}/M_{\text{med}} < 0.001$ correspond to the mass points where

Figure C.1: Cross section of the $pp \rightarrow H\chi\chi$ process as a function of $g_{hZ'Z'}$ for $m_{Z'} = 100$ GeV (left) and $m_{Z'} = 1$ TeV (right). The fit functions are shown in the text.
